Analysis 3.1. Comparison 3 Active workstation versus sit desk, Outcome 1 Mean difference in time spent sitting at work, follow-up short-term.

Analysis 3.2. Comparison 3 Active workstation versus sit desk, Outcome 2 Mean difference in time spent in inactive sitting at work, follow-up medium term.

Analysis 4.1. Comparison 4 Walking strategies versus no intervention, Outcome 1 Mean difference in time spent sitting at work, follow-up short term.

Analysis 4.2. Comparison 4 Walking strategies versus no intervention, Outcome 2 Mean difference in time spent sitting at work, follow-up medium-term.

Analysis 4.3. Comparison 4 Walking strategies versus no intervention, Outcome 3 Percentage of lost work productivity (WLQ Index Score) follow-up medium-term.

Analysis 5.1. Comparison 5 Short break versus long break, Outcome 1 Mean difference in time spent sitting at work, follow-up short-term.

Analysis 6.1. Comparison 6 Information, feedback and/or reminder versus information only or no intervention, Outcome 1 Mean difference in time in sitting bouts lasting 30 minutes or more, follow-up short-term.

Analysis 6.2. Comparison 6 Information, feedback and/or reminder versus information only or no intervention, Outcome 2 Mean difference in time spent sitting at work, follow-up medium-term.

Analysis 6.3. Comparison 6 Information, feedback and/or reminder versus information only or no intervention, Outcome 3 Mean difference in total time spent sitting (including sitting at and outside work), follow-up short-term.

Analysis 6.4. Comparison 6 Information, feedback and/or reminder versus information only or no intervention, Outcome 4 Mean difference in total time spent sitting (including sitting at and outside work), follow-up medium-term.

Analysis 6.5. Comparison 6 Information, feedback and/or reminder versus information only or no intervention, Outcome 5 Mean difference in time spent standing at work follow-up short-term.

Analysis 6.6. Comparison 6 Information, feedback and/or reminder versus information only or no intervention, Outcome 6 Work engagement (0-6 scale), follow-up medium-term.

Analysis 7.1. Comparison 7 Prompts plus information versus information alone, Outcome 1 Mean difference in time spent sitting at work, follow-up short-term.

Analysis 7.2. Comparison 7 Prompts plus information versus information alone, Outcome 2 Mean difference in time spent sitting at work, follow-up medium-term.

Analysis 7.3. Comparison 7 Prompts plus information versus information alone, Outcome 3 Mean difference in number of sitting bouts lasting 30 minutes or more, follow-up short-term.

Analysis 7.4. Comparison 7 Prompts plus information versus information alone, Outcome 4 Mean difference in time in sitting bouts lasting 30 minutes or more, follow-up short-term.

Analysis 7.5. Comparison 7 Prompts plus information versus information alone, Outcome 5 Mean difference in total time spent sitting (including sitting at and outside work), follow-up short-term.

Analysis 7.6. Comparison 7 Prompts plus information versus information alone, Outcome 6 Mean difference in time spent standing at work follow-up short-term.

Analysis 7.7. Comparison 7 Prompts plus information versus information alone, Outcome 7 Mean difference in energy expenditure, follow-up medium-term.

Analysis 8.1. Comparison 8 Computer prompts to step versus computer prompts to stand, Outcome 1 Mean difference in time spent sitting at work, follow-up short-term.

Analysis 8.2. Comparison 8 Computer prompts to step versus computer prompts to stand, Outcome 2 Mean difference in number of sitting bouts lasting 30 minutes or more, follow-up short-term.

Analysis 8.3. Comparison 8 Computer prompts to step versus computer prompts to stand, Outcome 3 Mean difference in time spent standing at work, follow-up short-term.

Analysis 8.4. Comparison 8 Computer prompts to step versus computer prompts to stand, Outcome 4 Mean difference in time stepping at work, follow-up short-term.

Analysis 9.1. Comparison 9 High personalised or contextualised information versus less personalised or contextualised information, Outcome 1 Mean difference in time in sitting bouts lasting 30 minutes or more, follow-up short-term.

Analysis 10.1. Comparison 10 Mindfulness training versus no intervention, Outcome 1 Mean difference in time spent sitting at work, follow-up medium-term.

Analysis 10.2. Comparison 10 Mindfulness training versus no intervention, Outcome 2 Work engagement (0-6 scale), follow-up medium-term.

ABSTRACT

Background
A large number of people are employed in sedentary occupations. Physical inactivity and excessive sitting at workplaces have been linked to increased risk of cardiovascular disease, obesity, and all-cause mortality.

Objectives
To evaluate the effectiveness of workplace interventions to reduce sitting at work compared to no intervention or alternative interventions.

Search methods
We searched the Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, Embase, CINAHL, OSH UPDATE, PsycINFO, ClinicalTrials.gov, and the World Health Organization (WHO) International Clinical Trials Registry Platform (ICTRP) search portal up to 9 August 2017. We also screened reference lists of articles and contacted authors to find more studies.

Selection criteria
We included randomised controlled trials (RCTs), cross-over RCTs, cluster-randomised controlled trials (cluster-RCTs), and quasi-RCTs of interventions to reduce sitting at work. For changes of workplace arrangements, we also included controlled before-and-after studies. The primary outcome was time spent sitting at work per day, either self-reported or measured using devices such as an accelerometer-inclinometer and duration and number of sitting bouts lasting 30 minutes or more. We considered energy expenditure, total time spent sitting (including sitting at and outside work), time spent standing at work, work productivity and adverse events as secondary outcomes.

Data collection and analysis
Two review authors independently screened titles, abstracts and full-text articles for study eligibility. Two review authors independently extracted data and assessed risk of bias. We contacted authors for additional data where required.
Main results
We found 34 studies - including two cross-over RCTs, 17 RCTs, seven cluster-RCTs, and eight controlled before-and-after studies - with a total of 3,397 participants, all from high-income countries. The studies evaluated physical workplace changes (16 studies), workplace policy changes (four studies), information and counselling (11 studies), and multi-component interventions (four studies). One study included both physical workplace changes and information and counselling components. We did not find any studies that specifically investigated the effects of standing meetings or walking meetings on sitting time.

Physical workplace changes
Interventions using sit-stand desks, either alone or in combination with information and counselling, reduced sitting time at work on average by 100 minutes per workday at short-term follow-up (up to three months) compared to sit-desks (95% confidence interval (CI) −116 to −84, 10 studies, low-quality evidence). The pooled effect of two studies showed sit-stand desks reduced sitting time at medium-term follow-up (3 to 12 months) by an average of 57 minutes per day (95% CI −99 to −15) compared to sit-desks. Total sitting time (including sitting at and outside work) also decreased with sit-stand desks compared to sit-desks (mean difference (MD) −82 minutes/day, 95% CI −124 to −39, two studies) as did the duration of sitting bouts lasting 30 minutes or more (MD −53 minutes/day, 95% CI −79 to −26, two studies, very low-quality evidence).

We found no significant difference between the effects of standing desks and sit-stand desks on reducing sitting at work. Active workstations, such as treadmill desks or cycling desks, had unclear or inconsistent effects on sitting time.

Workplace policy changes
We found no significant effects for implementing walking strategies on workplace sitting time at short-term (MD −15 minutes per day, 95% CI −50 to 19, low-quality evidence, one study) and medium-term (MD −17 minutes/day, 95% CI −61 to 28, one study) follow-up. Short breaks (one to two minutes every half hour) reduced time spent sitting at work on average by 40 minutes per day (95% CI −66 to −15, one study, low-quality evidence) compared to long breaks (two 15-minute breaks per workday) at short-term follow-up.

Information and counselling
Providing information, feedback, counselling, or all of these resulted in no significant change in time spent sitting at work at short-term follow-up (MD −19 minutes per day, 95% CI −57 to 19, two studies, low-quality evidence). However, the reduction was significant at medium-term follow-up (MD −28 minutes per day, 95% CI −51 to −5, two studies, low-quality evidence).

Computer prompts combined with information resulted in no significant change in sitting time at work at short-term follow-up (MD −10 minutes per day, 95% CI −45 to 24, two studies, low-quality evidence), but at medium-term follow-up they produced a significant reduction (MD −55 minutes per day, 95% CI −96 to −14, one study). Furthermore, computer prompting resulted in a significant decrease in the average number (MD −1.1, 95% CI −1.9 to −0.3, one study) and duration (MD −74 minutes per day, 95% CI −124 to −24, one study) of sitting bouts lasting 30 minutes or more.

Computer prompts with instruction to stand reduced sitting at work on average by 14 minutes per day (95% CI 10 to 19, one study) more than computer prompts with instruction to walk at least 100 steps at short-term follow-up.

We found no significant reduction in workplace sitting time at medium-term follow-up following mindfulness training (MD −23 minutes per day, 95% CI −63 to 17, one study, low-quality evidence). Similarly a single study reported no change in sitting time at work following provision of highly personalised or contextualised information and less personalised or contextualised information. One study found no significant effects of activity trackers on sitting time at work.

Multi-component interventions
Combining multiple interventions had significant but heterogeneous effects on sitting time at work (573 participants, three studies, very low-quality evidence) and on time spent in prolonged sitting bouts (two studies, very low-quality evidence) at short-term follow-up.

Authors’ conclusions
At present there is low-quality evidence that the use of sit-stand desks reduce workplace sitting at short-term and medium-term follow-ups. However, there is no evidence on their effects on sitting over longer follow-up periods. Effects of other types of interventions, including workplace policy changes, provision of information and counselling, and multi-component interventions, are mostly inconsistent. The quality of evidence is low to very low for most interventions, mainly because of limitations in study protocols and small
sample sizes. There is a need for larger cluster-RCTs with longer-term follow-ups to determine the effectiveness of different types of interventions to reduce sitting time at work.

**PLAIN LANGUAGE SUMMARY**

**Workplace interventions (methods) for reducing time spent sitting at work**

**Why is the amount of time spent sitting at work important?**

Time spent sitting and being physically inactive at work has increased in recent decades. Long periods of sitting may increase the risk of obesity, heart disease, and premature death. It is unclear whether interventions that aim to reduce sitting at workplaces are effective.

**The purpose of this review**

We wanted to find out the effects of interventions aimed at reducing sitting time at work. We searched the literature in various databases up to 9 August 2017.

**What trials did the review find?**

We found 34 studies conducted with a total of 3,397 employees from high-income countries. Sixteen studies evaluated physical changes in the workplace design and environment, four studies evaluated changes in workplace policies, 10 studies evaluated information and counselling interventions, and four studies evaluated multi-category interventions.

**Effect of sit-stand desks**

The use of sit-stand desks seems to reduce workplace sitting on average by 84 to 116 minutes per day. When combined with the provision of information and counselling, the use of sit-stand desks seems to result in similar reductions in sitting at work. Sit-stand desks also seem to reduce total sitting time (including sitting at work and outside work) and the duration of workplace sitting bouts that last 30 minutes or longer. One study compared standing desks and sit-stand desks but due to the small number of employees included, it does not provide enough evidence to determine which type of desk is more effective at reducing sitting time.

**Effect of active workstations**

Treadmill desks combined with counselling seem to reduce sitting time at work, while the available evidence is insufficient to conclude whether cycling desks combined with the provision of information reduce sitting at work more than the provision of information alone.

**Effect of walking during breaks or length of breaks**

The available evidence is insufficient to draw conclusions about the effectiveness of walking during breaks in reducing sitting time. Taking short breaks (one to two minutes every half hour) seems to reduce time spent sitting at work by 15 to 66 minutes per day more than taking long breaks (two 15-minute breaks per workday).

**Effect of information and counselling**

Providing information, feedback, counselling, or all of these reduces sitting time at medium-term follow-up (3 to 12 months after the intervention) on average by 5 to 51 minutes per day. The available evidence is insufficient to draw conclusions about the effects at short-term follow-up (up to three months after the intervention). The use of computer prompts combined with providing information reduces sitting time in the medium-term on average by 14 to 96 minutes per day. The available evidence is insufficient to draw conclusions about the effects in the short-term.

One study found that prompts to stand reduce sitting time more than prompts to step, on average by 10 to 19 minutes per day.

The available evidence is insufficient to conclude whether providing highly personalised or contextualised information is more or less effective than providing less personalised or contextualised information in reducing sitting time at work. The available evidence is also insufficient to draw conclusions about the effect of mindfulness training and the use of activity trackers on sitting at work.

**Effect of combining multiple interventions**

Combining multiple interventions seems to be effective in reducing sitting time and time spent in prolonged sitting bouts in the short-term and the medium-term. However, this evidence comes from only a small number of studies and the effects were very different across the studies.
Conclusions

The quality of evidence is low to very low for most interventions, mainly because of limitations in study protocols and small sample sizes. At present there is low-quality evidence that sit-stand desks may reduce sitting at work in the first year of their use. However, the effects are likely to reduce with time. There is generally insufficient evidence to draw conclusions about such effects for other types of interventions and for the effectiveness of reducing workplace sitting over periods longer than one year. More research is needed to assess the effectiveness of different types of interventions for reducing sitting at workplaces, particularly over longer periods.
### Summary of Findings for the Main Comparison

Alternative desks and workstations compared to sit-desks for reducing sitting at work

**Patient or population:** employees who sit at work  
**Setting:** workplace  
**Intervention:** alternative desks and workstations  
**Comparison:** sit-desks

#### Comparison: sit-stand desk with or without information and counselling versus sit-desk

- **Mean difference in time spent sitting at work, short-term follow-up (up to 3 months)**  
  - The mean difference in time spent sitting at work (short-term follow-up) was 364 minutes  
  - MD 100 minutes lower (116 lower to 84 lower)  
  - **323** (10 studies: 4 RCTs, 2 crossover RCTs, 4 CBAs)  
  - ⬤⬤⬤  
  - **LOW 12**  
  - Subgroup analysis showed no difference in effect between sit-stand desks used alone or in combination with information and counselling. Restricting the analysis to RCTs only did not show any difference in effect either

- **Mean difference in time in sitting bouts lasting 30 minutes or more, short-term follow-up**  
  - The mean difference in time in sitting bouts lasting 30 minutes or more (short-term follow-up) was 167 minutes  
  - MD 53 minutes lower (79 lower to 26 lower)  
  - **74** (2 CBAs)  
  - ⬤⬤⬤⬤  
  - **VERY LOW 23**

#### Comparison: treadmill desk combined with counselling versus sit-desk

- **Mean difference in time spent sitting at work, short-term follow-up (up to 3 months)**  
  - The mean difference in time spent sitting at work (short-term follow-up) was 342 minutes  
  - MD 29 minutes lower (55 lower to 2 lower)  
  - **31** (1 RCT)  
  - ⬤⬤⬤  
  - **LOW 24**
Mean difference in time in sitting bouts lasting 30 minutes or more, short-term follow-up - not reported

Comparison: cycling desk + information and counselling versus sit-desk + information and counselling

Mean difference in time spent in inactive sitting at work, medium-term follow-up (from 3 to 12 months)
The mean difference in time spent in inactive sitting at work (medium-term follow-up) was 413 minutes
MD 12 minutes lower (24 lower to 1 higher)
54 (1 RCT) ⊕⊕⃝⃝

* The risk in the intervention group (and its 95% confidence interval) is based on the assumed risk in the comparison group and the relative effect of the intervention (and its 95% CI).

GRADE Working Group grades of evidence
High certainty: We are very confident that the true effect lies close to that of the estimate of the effect
Moderate certainty: We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different
Low certainty: Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect
Very low certainty: We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

1 Of the six RCTs, five were at high risk of bias. The non-randomised controlled before-and-after study/studies were also at high risk of bias; downgraded one level
2 Imprecision with wide confidence intervals, small sample size; downgraded one level
3 Unconcealed allocation, unblinded outcome assessment and attrition bias; downgraded two levels
4 Unblinded outcome assessment; downgraded one level
5 Unblinded outcome assessment and attrition bias; downgraded one level
Description of the condition

Sedentary behaviour, especially sitting, has attracted great interest from media, government agencies and researchers in recent years. Energy expenditure in various tasks can be expressed in metabolic equivalents (METs). One MET is equivalent to resting energy expenditure, i.e. the energy cost of resting quietly, defined as an oxygen uptake of 3.5 mL kg$^{-1}$ min$^{-1}$ (Ainsworth 2000). Sitting at work and conducting work tasks whilst seated usually involves energy expenditure of 1.5 METs or less. Reduction in time spent sitting usually results in increased levels of physical activity of light to moderate intensity, such as standing or walking (Mansoubi 2014).

The nature of office work has changed since the year 2000 in such a way that workers do not have to move often from their work stations (VicHealth 2012). Advancement in technology (e.g. robotics, computers) has led to a decrease in physical strain at workplaces (Craig 2002). Consequently, workers in some settings have become less physically active at their workplace compared to their leisure time (Franklin 2011; McCrady 2009; Parry 2013; Thorp 2012; van Uffelen 2010). Since the 1960s, in the USA and the UK for example, population levels of occupational physical activity have declined by more than 30% (Ng 2012). A large decline in occupational physical activity has also been found in low- and middle-income countries, such as Brazil and China (Ng 2012). This decline in occupational physical activity can largely be attributed to an increase in time spent sitting at the workplace.

It has been found that office-based employees spent 66% of their total working time sitting, with 5% of all sitting events and 25% of total sitting time spent in bouts longer than 55 minutes (Ryan 2011). Studies have shown that excessive time spent sitting at work may increase the risk of cardiovascular disease, obesity, diabetes, and all-cause mortality, even if one is engaged in recommended levels of physical activity during their leisure time (Chau 2014a; Craft 2012; Dunstan 2011). Estimates show a 5% increase in the risk of obesity and 7% increase in the risk of diabetes associated with every two-hour per day increase in sitting time at work (Hu 2003). It has also been estimated that those who sit for eight to 11 hours per day are at a 15% increased risk of death in the next three years than those who sit for less than four hours per day, whilst the risk increases to 40% for those who sit for more than 11 hours per day (Van der Ploeg 2012). In Bey 2003, it is hypothesised that replacing sitting with physical activity of light (from 1.5 METs to 3 METs) to moderate (3 METs to 6 METs; Ainsworth 2011) intensity improves glucose and lipid metabolism. Another study, Duivivier 2013, has also suggested that benefits may be greater when sitting is replaced with activity of light to moderate intensity, such as standing and walking, than when it is replaced with vigorous cycling of equal energy expenditure. This may indicate that, in interventions to reduce sedentary behaviour, changing posture may be equally or even more important than increasing energy expenditure.

Description of the intervention

It is estimated that 60% of the world’s population is part of the workforce and spends on average 60% of their waking hours at work (WHO/WEF 2008). Thus, it is possible to influence health behaviour of a large proportion of the adult population worldwide through workplace interventions.

Workplaces have the advantage of having the potential for creating in-built social support, that is, active collaboration of employees in making sustainable changes to attain a healthy lifestyle, which may reduce the degree of individual effort and motivation needed to make behavioural changes. Therefore, the changes in lifestyle achieved at work are thought to be sustainable in the long term (Plomnikoff 2012).

Workers can be encouraged to be more physically active through changes in the workplace environment and design. A conventional sitting desk can be replaced or supplemented with: a sit-stand desk; a so-called ‘hot desk’ that is height-adjustable and allows its user to alternate posture between sitting and standing (Alkhajah 2012; Gilson ND 2012; Straker 2013); a vertical workstation that allows the use of a personal computer while walking on a treadmill at a self-selected velocity (Levine 2007); a stepping/pedalling desk exercise machine placed under the desk that allows the user to step or pedal while being seated (McAlpine 2007); an inflated balloon chair; or a therapy ball (Beers 2008; USPTO 2000). Replacing conventional office chairs with inflated balloon chairs makes the act of sitting more physically demanding by increasing the need to use the abdominal, back, leg and thigh muscles to remain upright and maintain balance.

Time spent in sedentary behaviour can theoretically also be reduced by changing the layout of workplaces, for example by placing printers further away from desks. Office work can also be made more physically demanding by forming walking or other exercise groups like dance or gym groups during work time (Ogilvie 2007; Thogersen-Ntoumanis 2013), and by encouraging employees to walk around office buildings during breaks or to take a walk to communicate with fellow employees instead of using the telephone or email. The practices and policies of workplaces can be changed by incorporating periodic breaks within the organisational schedule including short bouts of physical activity (e.g. five to 15-minute activity bouts) or by conducting walking or standing meetings (Commissaris 2007). Meeting rooms can be equipped with sit-stand desks so that employees can choose to stand during meetings, if they wish (Atkinson 2014). These changes in workplace practice and policy have the potential of providing an opportunity to a large number of people, who mostly sit at work, to reduce their sitting time.
Workers can also be made aware of the importance of changing their sitting behaviour by the provision of information, such as by motivational prompts to sit less at the workstation, via e-health interventions that encourage and remind workers to sit less or interrupt prolonged periods of sitting (Cooley 2014; Evans 2012; Pedersen 2013), or by distributing leaflets with messages like “Sit less, move more” that highlight the risks associated with sitting. An e-health intervention consists of information that is delivered electronically like emails, point-of-choice prompts, or any message periodically displayed on the computer screen. Informational interventions can also be delivered by trained counsellors in an interactive manner, where, as part of counselling sessions, they find out about worker’s interests and provide the worker different options on how to reduce sedentary behaviour (Opdenacker 2008). There are some potential drawbacks to these interventions. The performance and productivity of workers at sitting jobs might be decreased when walking at the workplace is encouraged and the employees more frequently leave their desks. Workers using a treadmill desk need to be careful not to trip or fall, and thus divide their attention between work and safety, which might compromise their productivity (Tudor-Locke 2013). In addition, fine motor skills like mouse handling accuracy, math problem solving skills, and perceived work performance seem to decrease with treadmill and cycling desks (Commissaris 2014; John 2009). This decrease in efficiency might be due to learning effects, that is, becoming acquainted with new modes of work.

How the intervention might work

According to ecological models, successful strategies for reducing sedentary behaviour include:

- providing access to infrastructures for reducing sedentary behaviour;
- increasing awareness and understanding of the importance of and methods for reducing sedentary behaviour; or
- using social networks and organisational support to inform and encourage changes in policies and norms related to sedentary behaviour (Sallis 2006).

Based on this definition, we envisage three different ways (in isolation or conjunction with each other) in which interventions could work to decrease sitting at workplaces.

Physical changes in the workplace design and environment

If employees are using a conventional desk or chair in the workplace, provision of new types of work desks or chairs can make them aware of the possibilities such new equipment offers to decrease sitting, and they may be tempted to try them. This would hypothetically replace sitting with some other activity, while allowing the usual tasks to be carried out with the same efficiency. Changing the layout of the workplace by, for example, placing printers away from desks would force employees to stand up and walk to obtain their printouts.

Policies to change the organisation of work

Organisational policies could support the formation of walking or exercise groups at the workplace or conducting walking meetings. Formation of walking or exercise groups or conducting walking meetings, might help individuals to reduce sitting and might also help them encourage each other to adopt new behaviours. The provision of purposive short breaks (with the aim of reducing sitting) might help workers engage in such activities more frequently. The breaks might also encourage employees to take a walk to communicate with colleagues instead of using the telephone or email. Standing meeting rooms would provide an opportunity for office employees to reduce their sitting time.

 Provision of information and counselling

Sedentary workers could be made aware of the importance of reducing their time spent in sedentary behaviour. They could be informed about health risks and the benefits of reducing time spent sitting and replacing it with time spent in a more physically demanding behaviour. In Wilks 2006, it was found that employees who had received information regarding the health risks of sitting were more likely to use a sit-stand desk more frequently than those who had not. Even if people are aware of the adverse effects of excessive sitting, and have access to facilities and programs to decrease sitting, they might still find difficulties in adapting to new behaviour. It requires conscious effort for a person to interrupt their normal sitting behaviour and engage in physical activity while at work. To facilitate behaviour change, people could be provided with point-of-choice prompts or counselling, which might enable individuals to evaluate their behavioural choices and motivate them to adopt healthy ones. Points-of-choice prompts can be delivered through various means such as signs, emails, text messages, or telephone calls, to motivate change of behaviour. A prompting software can be installed on an employee’s personal computer, so that a one-minute reminder to take a break appears on their screen every 30 minutes (Evans 2012).

Why it is important to do this review

Interventions to decrease sitting at work are becoming increasingly popular, but it is unclear whether they are effective in the long term or not (Healy 2013). Therefore, there is a need to evaluate whether sitting at work can be reduced by interventions, and to compare the effectiveness of various types of such interventions. Although some studies have shown that sit-stand desks and walking strategies have been useful in reducing sitting, no significant difference in the duration of individual bouts of sitting was found in Straker 2013. Another study did not find a significant effect of
strategies to increase walking on sitting behaviour (Gilson 2009), while in Evans 2012, it was found that point-of-choice prompting software along with education was superior to education alone. Such inconsistency in the findings from individual studies means it is unclear whether workplace interventions for reducing sitting are effective, and whether different types of interventions differ in their effectiveness. Possibly because of the variation in results across studies, recommendations for reducing sitting at work vary. In recent years, several countries, such as the UK and Australia (Australian Government 2014; Department of Health 2011), have incorporated sedentary behaviour recommendations as part of their physical activity guidelines. These guidelines, however, only propose potential strategies for reducing sitting time without quantifying the recommended total duration of sitting time. In 2015, an international group of experts recommended that desk-based employees should aim towards accumulating two hours of standing and light activity (light walking) per day during working hours, eventually progressing to a total accumulation of four hours per day. To achieve this, they recommended breaking up sitting time with standing by using sit-stand desks or by taking short active standing breaks (Buckley 2015). While all these guidelines stress the evidence of the adverse effects of sitting on health, there is little evidence that different interventions aiming to reduce sitting can help individuals meet any of these recommendations. Furthermore, since this topic is of increasing interest, it is likely that the availability of evidence will increase in the near future. A Cochrane systematic review will ensure timely updating of this information for decision makers.

**OBJECTIVES**

To evaluate the effectiveness of workplace interventions for reducing sitting at work compared to no intervention or alternative interventions.

**METHODS**

**Criteria for considering studies for this review**

**Types of studies**

We included randomised controlled trials (RCTs), cross-over RCTs, cluster-RCTs, and quasi-RCTs. Quasi-RCTs are trials that allocate participants to the intervention or control group using a method of randomisation that is not actually random. At workplaces, interventions operate at group level and may therefore be difficult to deliver to individuals (Ijaz 2014). Since it is more difficult to randomise units when the intervention is implemented at a higher aggregate level, we also included controlled before-and-after studies (CBAs) that used a concurrent control group for the interventions that aimed to change workplace arrangements.

**Types of participants**

We included all studies conducted with participants aged 18 years or more, whose occupations involved spending the majority of their working time sitting at a desk, such as administrative workers, customer service operators, help-desk professionals, call-centre representatives, and receptionists. We excluded studies that addressed transportation work. People working in the transportation industry (such as taxi drivers, truck drivers, bus drivers, and airline pilots) and who operate heavy equipment (such as crane operators and bulldozer operators) are also exposed to prolonged sitting, but current technology provides very limited options for implementing interventions to decrease sitting in such occupations. Reducing sitting in people who work in the transportation industry and operate heavy machinery would require specific interventions that could be the scope of another review.

**Types of interventions**

**Intervention**

**Physical changes in the workplace design and environment**

- Changes in the layout of the workplace, such as placing printers away from office desks.
- Changes in desks enabling more physical activity, such as the use of sit-stand desks, vertical workstations on treadmills, desk cycle/cycling desks, or stepping devices.
- Changes in chairs enabling more physical activity, such as inflated balloon chairs or therapy balls.

**Policies to change the organisation of work**

- Walking meetings and walking or other exercise groups during work time.
- Breaks (periodic, frequent, or purposive) to sit less, stand up, and take an exercise break.
- Sitting diaries.

**Provision of information and counselling**

- Signs or prompts at the workplace (e.g. posters) or at the workstation (computer).
- E-health intervention.
- Distribution of leaflets.
• Counselling (face to face, by email, or by telephone).

Multi-component interventions
• Interventions that included elements from all the three above-mentioned categories.

Comparison
We compared the interventions described above with no intervention or with other interventions.

Types of outcome measures

Primary outcomes
We included studies that evaluated sitting at work measured either as:
• self-reported time spent sitting at work by questionnaires; or
• device-based measures of sitting assessed by means of an accelerometer-inclinometer, which assesses intensity of physical activity and body posture (Kanoun 2009; Kim 2015); or
• self-reported or device-based measures of time spent in prolonged sitting bouts (e.g. 30 minutes or more) and number of such bouts.

Secondary outcomes
• Estimated energy expenditure in metabolic equivalent (MET) hours per workday as a proxy measure to detect changes in sitting time.
• Self-reported or device-measured total time spent sitting, including sitting at and outside work.
• Self-reported or device-measured time spent standing and stepping at work.
• Work productivity.
• Adverse events including any reported musculoskeletal symptoms due to prolonged standing as a possible side-effect of using a sit-stand desk.

Search methods for identification of studies

Electronic searches
We searched for all eligible published and unpublished trials in any language. We were prepared to translate non-English language abstracts for potential inclusion. Our search strategy was based on types of study population, types of study design, work-related aspects, and outcomes related to sitting, and it consisted of keywords generated with the help of a thesaurus, such as ‘seated posture’. We searched the following electronic databases from inception to 9 August 2017 for identifying potential studies:
• Cochrane Central Register of Controlled Trials (CENTRAL; Appendix 1);
• MEDLINE (searched through Ovid; Appendix 2);
• Cumulative Index to Nursing & Allied Health Literature (CINAHL; Appendix 3);
• Occupational Safety and Health Database (OSH UPDATE; Appendix 4);
• Excerpta Medica database (Embase; Appendix 5);
• PsycINFO (searched through Ovid; Appendix 6);
• ClinicalTrials.gov (http://clinicaltrials.gov/; Appendix 7); and
• World Health Organization (WHO) International Clinical Trials Registry Platform (ICTRP) search portal (http://apps.who.int/trialsearch/; Appendix 8).

Data collection and analysis

Selection of studies
Two review authors (NS, KKH) independently screened titles and abstracts of the documents found in our systematic search, to identify potential studies for inclusion. The same authors marked citations as ‘retrieve’ (eligible or potentially eligible/unclear) or ‘do not retrieve’. We retrieved full-text study reports or publications for all citations considered potentially relevant. Two authors (NS, KKH) independently assessed the retrieved full-texts to identify eligible studies for inclusion. We recorded reasons for exclusion of ineligible studies. We resolved disagreements through discussion or, if required, we consulted a third author (SI). We identified and excluded duplicates and collated multiple reports of the same study so that each study rather than each report was the unit of interest in the review. We recorded the selection process in sufficient detail to create a Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow diagram (Moher 2009).

Data extraction and management
We used a data collection template to extract study characteristics and outcome data. We extracted the following information.
• Methods: study location, date of publication, type of study design, study setting.
• Participants: number randomised or recruited, mean age or age range, gender, inclusion and exclusion criteria of the trial, occupation, number of withdrawals, similarity of study groups in age, gender, occupation, and sitting time at baseline.
• Interventions: description of intervention methods and randomised groups, duration of active intervention, duration of follow-up, and description of comparisons, interventions and co-interventions.
• Outcomes: description of primary and secondary outcomes and their assessment methods.
• Notes: source of funding for the trial and potential conflicts of interest of trial authors.

Two review authors (NS and either VH or SI) independently extracted outcome data from the included studies. We noted in the Characteristics of included studies table when trial authors did not report outcome data in a usable way. We resolved disagreements by consensus or by involving a third author (either SI or VH). One review author (NS) transferred data into Cochrane’s statistical software, Review Manager 5 (Review Manager 2014). We double-checked that we had entered the data correctly. For this purpose we tabulated extracted information about studies in a spreadsheet before entry into Review Manager. A review author (JV) spot-checked a random 20% of extracted data for accuracy against the trial report.

Assessment of risk of bias in included studies
Two review authors (NS and either VH or SI) independently assessed risk of bias for each study using the criteria outlined in the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2011). We resolved disagreements by discussion or by involving another author (ZP). We assessed the included studies’ risk of bias according to the following domains.
• Random sequence generation
• Allocation concealment
• Blinding of participants and personnel
• Blinding of outcome assessment
• Incomplete outcome data
• Selective outcome reporting
• Validity of outcome measure
• Baseline comparability/imbalance for age, gender and occupation of study groups

We graded each potential source of bias as high, low, or unclear and provided a quote from the study report together with a justification for our judgment in the ‘Risk of bias’ tables. We summarised the risk of bias judgements across different studies for each of the domains. Where information on risk of bias related to unpublished data or correspondence with a trialist, we noted it as such in the ‘Risk of bias’ tables.

We judged studies as being at low risk for selective outcome reporting, if the publications of the trial followed what had been planned and had been registered in international databases (trial registries), such as ClinicalTrials.gov, Australia and New Zealand Clinical Trials Registry (anzctr.org.au/), or Netherlands Trial Registry (trialregister.nl). We judged the studies that were not registered in trial registries as being at low risk for selective outcome reporting if they had reported all the outcomes mentioned in their methods section.

We judged a study to be at low risk of bias overall when the study included a sufficiently detailed description of its random sequence generation, allocation concealment, blinding of outcome assessment, complete outcome data, no selective outcome reporting, and valid outcome measures, that is, all the domains had a low risk of bias. We judged a study to have a high risk of bias when it reported a feature that would be judged as having a high risk of bias in any one of the eight domains. We did not assess blinding of participants or study personnel for risk of bias, as it is very difficult to blind either of them in studies that are trying to modify sedentary behaviour.

Measures of treatment effect
We entered the outcome data for each study into the data tables in Review Manager to calculate the pooled treatment effects. We used risk ratios (RRs) for dichotomous outcomes and mean differences (MDs) for continuous outcomes. Where only effect estimates and their 95% confidence intervals (CIs) or standard errors were reported in studies, we entered these data into Review Manager using the generic inverse variance method.

Unit of analysis issues
For cluster-RCTs that did not present results accounting for clustering effect, we calculated these assuming a large intra-cluster correlation coefficient of 0.10. We based this assumption on a realistic estimate by analogy on studies about implementation research (Campbell 2001). We transformed all measurement units for sitting at work into minutes per eight-hour workday where needed and possible, and assumed the data referred to a five-day work week, if this was not reported.

Dealing with missing data
We contacted researchers or study sponsors to verify key study characteristics and obtain missing information or full-text reports. When we did not find a full study report even after contacting authors listed in the respective abstract, we categorised the references as Studies awaiting classification.

For missing data not obtained from authors, such as standard deviations, we calculated these following the advice in the Cochrane Handbook section 16.1.2 (Higgins 2011). We tested the inclusion of studies with missing data and any imputations in sensitivity analyses.

Assessment of heterogeneity
We assessed clinical homogeneity of the results of included studies based on similarity of populations, interventions, outcomes, and follow-up times. We considered populations to be similar when the participants were 18 years or older and their occupations involved
sitting for a major part of their working time. We considered interventions to be similar when their working mechanisms were similar, for example, replacing sit-desks with sit-stand desks (see Types of interventions). We regarded follow-up times of three months or less as short-term, between three months and one year as medium-term, and more than one year as long-term.

We quantified the degree of heterogeneity using the I² statistic, where an I² value of 25% to 50% indicates a low degree of heterogeneity, 50% to 75% a moderate degree of heterogeneity, and more than 75% a high degree of heterogeneity. If we identified moderate to high heterogeneity, we reported it and explored possible causes by pre-specified subgroup analyses.

**Assessment of reporting biases**

When ten or more studies were included in a meta-analysis, we tested for the effect of small studies using a funnel plot.

**Data synthesis**

We analysed the effects of interventions in the categories defined in Types of interventions: physical changes in the workplace design and environment (changes in desks; changes in chairs); policies to change the organisation of work (supporting social environment and policies for breaks); or provision of information and counselling. We pooled effect size estimates from individual studies using Review Manager 5 (Review Manager 2014). We considered studies to be heterogeneous, and therefore used a random-effects model to calculate pooled effect sizes.

We calculated the prediction interval for the outcome sitting time at work for sit-stand desks compared to sit-desks. Prediction intervals give an estimate of the effect of a new study based on the heterogeneity of effects of studies included in the meta-analysis (Higgins 2009; IntHout 2016).

**Summary of findings' table**

We reported time spent sitting at work and time spent in sitting bouts of 30 minutes or more at short-term follow-up in the ‘Summary of findings’ table. Where study authors did not report effects in the short-term follow-up for the outcomes mentioned above, we presented results at medium-term follow-up. We only reported the most relevant comparisons. We used the Grading of Recommendations Assessment, Development and Evaluation (GRADE) considerations (study limitations, consistency of effect, imprecision, indirectness, and publication bias) to assess the quality of the body of evidence that contributed data to the meta-analyses for these outcomes (Higgins 2011). We justified all decisions to downgrade or upgrade the quality of evidence using footnotes and we made comments to aid readers' understanding of the review where necessary.

**Subgroup analysis and investigation of heterogeneity**

If sufficient data become available in future updates of this review we will conduct the following subgroup analyses for the primary outcome of time spent sitting at work.

- Age: we will compare studies conducted in participants aged 18 to 40 years with studies where all participants were aged 41 years or older, as the probability of maintaining good health and fitness diminishes with older age (AIHW 2008). Older employees might also expect a larger health benefit due to a reduction in sitting (Manini 2015).

- Types of outcome measure: we will carry out a subgroup analysis by type of outcome measure, that is, self-reported (e.g. questionnaire, log book) versus accelerometer/inclinometer versus Ecological Momentary Assessment.

- Types of intervention: we will carry out a subgroup analysis for different interventions that have been pooled under a broader category of intervention.

Similarly, we will assess the robustness of our results by excluding studies we judge to have a high risk of bias from all meta-analyses.

**R E S U L T S**

**Description of studies**

See: Figure 1, Characteristics of included studies, Characteristics of excluded studies, Characteristics of studies awaiting classification, and Characteristics of ongoing studies.
Figure 1. PRISMA study flow diagram

4,480 studies excluded

63 studies excluded
- 13 studies - not RCT or CBA
- 15 studies - did not report workplace sitting
- 5 studies - not conducted in workplace setting
- 6 ongoing studies
- 1 study awaiting classification

Full text assessment: 94 studies

14 studies newly included

34 studies included in qualitative synthesis

19 studies included in quantitative synthesis (meta-analysis)
Results of the search

We conducted systematic searches in selected electronic databases and grey literature sources. We identified altogether 12,368 references in the initial search (December 2013) and the first search update (June 2015), and retrieved a total of 92 references for full-text scrutiny. Of these, we excluded 72 articles and included 20 studies in the previous published version of this review. For this update, we searched the electronic databases from June 2015 until 9 August 2017. The updated search identified a total of 6,040 references, as outlined in Figure 1; 396 from CENTRAL (Appendix 1; 9 August 2017); 2683 from MEDLINE (searched through Ovid, Appendix 2; 9 August 2017); 849 from CINAHL (Appendix 3; 9 August 2017); 108 from OSH UPDATE (Appendix 4; 9 August 2017); 1099 from Embase (Appendix 5; 9 August 2017); 899 from PsycINFO (Appendix 6; 9 August 2017); 4 from Clinical-Trials.gov (Appendix 7; 9 August 2017); and 2 from the WHO trials search portal (Appendix 8; 9 August 2017). Removal of duplicates reduced the total number of references to 4,534. Based on their titles and abstracts, we selected 54 of these references for full-text reading. Out of these, we excluded 33 studies. Six studies are ongoing and one study was not available in full text so we classified it as a study awaiting classification. This resulted in 14 studies being included in this review update in addition to the 20 studies already included in the previous version of the review.

Included studies

Study design

Out of the 34 included studies, 17 are RCTs, two are cross-over RCTs, seven are cluster-RCTs, and eight are controlled before-and-after studies with concurrent controls. See Characteristics of included studies for further details. Although the authors described their studies as quasi-RCTs, we categorised Alkhajah 2012, and Neuhaus 2014a, as controlled before-and-after studies because the risk of baseline differences for studies with only two clusters is very high. Only one cluster trial reported unadjusted results (De Cocker 2016). Therefore we adjusted their results for the design effect following the methods stated in Section 16.3 of the Cochrane Handbook for Systematic Reviews of Interventions for the calculations (Higgins 2011).

We considered randomised and non-randomised studies as similar if there were no considerable differences in their effect estimates (Alkhajah 2012; Chau 2014; Chau 2016; Dutta 2014; Graves 2015; Healy 2013; Li 2017; MacEwen 2017; Neuhaus 2014a; Tobin 2016), but explored any potential differences in a subgroup analysis.

For meta-analyses that included two arms of the same study, we halved the number of participants in the control group (Coffeng 2014; De Cocker 2016; Neuhaus 2014a). For Coffeng 2014, we used the unadjusted results at twelve months follow-up. In other comparisons we used the adjusted values with the generic inverse variance method. One included study (Neuhaus 2014a) reported only MDs and standard errors and the authors could not provide raw data, so we could not adjust the number of participants. In this case we modelled the means and standard deviations from the intervention and the control group in Review Manager as closely to the raw data as possible to achieve the same MD and standard error. Then we halved the number of participants in the control group and entered the resulting standard errors into Review Manager.

Participants

The included studies were conducted with a total of 3,397 employees. The sample sizes of included trials ranged from 16 in the smallest study (Chau 2016), to 523 in the largest one (Verweij 2012), with a median of 44. Studies included workers from the public and private sectors, with nine studies including researchers and other academic staff, two studies including health workers, and 23 including employees in private companies.

Gender

Participants in 20 studies were predominantly women (Carr 2015; Danquah 2017; De Cocker 2016; Donath 2015; Dutta 2014; Evans 2012; Gao 2015; Gilson 2009; Graves 2015; Healy 2016; Kress 2014; Li 2017; MacEwen 2017; Mailey 2016; Pickens 2016; Priebel 2015; Schuna 2014; Swartz 2014; Tobin 2016; Urda 2016). In the remaining 14 studies the proportions of women and men did not differ significantly.

Country

The studies were conducted in Australia, the USA, Canada, and several high-income countries in Europe.

Interventions

1. Physical changes in the workplace design and environment

Sixteen studies evaluated the effectiveness of individual workspace modifications on workplace sitting time (Alkhajah 2012; Carr 2015; Chau 2014; Chau 2016; Dutta 2014; Gao 2015; Graves 2015; Healy 2013; Kress 2014; Pickens 2016; Li 2017; MacEwen 2017; Neuhaus 2014a; Schuna 2014; Sandy 2016; Tobin 2016)
Sit-stand desk

Twelve studies assessed the effectiveness of interventions using sit-stand desks. The interventions using a sit-stand desk were assessed independently (Alkhajah 2012; Chau 2014; Dutta 2014; Gao 2015; MacEwen 2017; Neuhaus 2014a), and in combination with information and counselling (Chau 2016; Graves 2015; Healy 2013; Li 2017; Neuhaus 2014a; Tobin 2016). One study compared the effectiveness of multiple types of interventions, including: 1) sit-stand desk; 2) ergonomic training; 3) sit-stand desk combined with ergonomic training; and 4) standard sit-desk (Sandy 2016).

Standing desk

Two studies compared the effectiveness of a standing desk intervention and a sit-stand desk intervention (Kress 2014; Pickens 2016).

Active workstation

Two studies evaluated the effectiveness of interventions using active workstations (i.e. desks that cause significant increase in energy expenditure compared to conventional sit-desks). One study assessed the effectiveness of a treadmill desk (Schuna 2014), while another assessed the effectiveness of a cycle desk (Carr 2015).

2. Policy to change the organisation of work

Two studies evaluated the effectiveness of walking strategies (Gilson 2009; Puig-Ribera 2015). The first evaluated the effectiveness of route and incidental walking on office employees’ sitting time at work (Gilson 2009). The route-based walking intervention was intended to increase the amount of brisk, sustained walking during work breaks. The incidental walking intervention aimed to increase walking and talking to colleagues, instead of sending emails or making telephone calls, and standing and walking during meetings, instead of sitting at desks. The other study evaluated the effectiveness of incidental movement and short (5 to 10 minutes) and longer (10+ minute) walks on office employees’ sitting time at work (Puig-Ribera 2015). One study evaluated the effectiveness of planned daily breaks from sitting (Mailey 2016). They compared taking short breaks (one to two minutes every half hour) to taking long breaks (two 15-minute breaks per workday).

3. Provision of information and counselling

Information and feedback

One study evaluated the effectiveness of personalised computer-tailored feedback and generic feedback intervention in reducing sitting time in office employees (De Cocker 2016). Another compared the effectiveness of delivering emails containing psychosocial materials and other available resources that were based on constructs of Social Cognitive Theory relating to decreasing sedentary behaviours at work, to delivering emails concerning general health topics (Gordon 2013). In Priebé 2015, the effectiveness of providing highly personalised or contextualised information was compared with the effectiveness of providing less personalised or contextualised information.

Counselling

In Verweij 2012, the effectiveness of counselling by occupational physicians (highly trained specialists who provide health services to employees and employers (AFOEM 2014)) was compared with usual care in decreasing sitting time in office employees. Another study evaluated the effectiveness of group motivational interviewing (i.e. a counselling style that stimulates behavioural change by focusing on exploring and resolving ambivalence in a group) by occupational physicians on office employees’ sitting time (Coffeng 2014).

Computer prompts

Four studies evaluated the effectiveness of computer prompts combined with information, compared to information alone, for decreasing sitting time in office employees (Donath 2015; Evans 2012; Pedersen 2013; Urda 2016). Computer prompts offer an opportunity to employees to choose and engage in a short ‘burst’ of physical activity such as standing or walking. One study, Swartz 2014, assessed the effect of hourly prompts (computer-based and wrist worn) to stand up or to step on reducing sitting time in office employees. One study, Brakenridge 2016, assessed the effectiveness of activity tracker combined with organisational support compared to organisational support only. One study, van Berkel 2014, evaluated the effectiveness of mindfulness training in decreasing sitting time in office employees. The mindfulness intervention consisted of homework exercises and information through emails.

4. Multi-component interventions

Four studies evaluated the effectiveness of combining multiple interventions on sitting at work (Coffeng 2014; Danquah 2017; Ellegast 2012; Healy 2016). In Coffeng 2014, the effectiveness of combining multiple environmental interventions with Group Motivational Interviewing
(GMI) was assessed. The multi-component environmental intervention consisted of: 1) the Vitality in Practice (VIP) Coffee Corner Zone, where a workplace coffee corner was modified by adding a bar with bar chairs, a large plant, and a giant wall poster (a poster visualizing a relaxing environment, e.g. wood, water, and mountains); 2) the VIP Open Office Zone, where an office was modified by introducing exercise balls and curtains to divide desks in order to reduce background noise; 3) the VIP Meeting Zone, where conference rooms were modified by placing a standing table and a giant wall poster; and 4) the VIP Hall Zone, where table tennis tables were placed and lounge chairs were introduced in the hall for informal meetings. In addition, footsteps were placed on the floor in the entrance hall to promote stair walking. In Ellegast 2012, the effectiveness of multiple environmental interventions in combination with a walking strategy were assessed. The intervention consisted of measures aiming to change workplace environment (e.g. sit-stand tables) and behaviour (e.g. using pedometers to provide activity feedback, face-to-face motivation for lunch walks, and an incentive system for bicycle commuting or sports activities).

The study by Danquah and colleagues evaluated the effectiveness of a multi-component intervention comprising of organisational strategies (support from management), environmental strategies (installation of standing meeting tables), and individual strategies (a lecture and email or text messages) (Danquah 2017).

The fourth study evaluated the effectiveness of a multi-component intervention comprising of organisational strategies (consultation and support from the management), environmental strategies (sit-stand desk), and individual strategies (coaching and goal setting) (Healy 2016).

Type of control group

No intervention

Twenty-three included studies used a ‘no intervention’ control group (Alkhajah 2012; Chau 2014; Chau 2016; Coffeng 2014; Danquah 2017; De Cocker 2016; Dutta 2014; Ellegast 2012; Gao 2015; Gilson 2009; Graves 2015; Healy 2013; Healy 2016; Li 2017; MacEwen 2017; Neuhaus 2014a; Puig-Ribera 2015; Sandy 2016; Schuna 2014; Tobin 2016; Urda 2016; van Berkel 2014; Verweij 2012).

Other controls

In Carr 2015, a cycle desk in combination with information and counselling was compared with information and counselling only, resulting in the net effect of a cycle desk. In Kress 2014, and Pickens 2016, the effectiveness of standing desks was compared with the effectiveness of sit-stand desks. Three studies compared computer prompts combined with information with information only, resulting in the net effect of computer prompts (Donath 2015; Evans 2012; Pedersen 2013). In Gordon 2013, the effectiveness of delivering emails concerning general health topics was compared with delivering emails containing psychosocial materials and other available resources based on constructs of the Social Cognitive Theory relating to decreasing sedentary behaviours at work. In Swartz 2014, computer-based and wrist-worn prompts, combined with instruction to stand, were compared with the same prompts combined with instruction to walk at least 100 steps. In Priebe 2015, highly personalised information was compared with less personalised information. One study evaluated the effectiveness of short breaks compared to long breaks (Mailey 2016). Another study compared the effectiveness of activity trackers combined with organisational support with organisational support only (Brakenridge 2016).

Outcomes

Total time spent sitting at work

Total time spent sitting at work was used as an outcome variable in 24 studies (Alkhajah 2012; Brakenridge 2016; Chau 2014; Chau 2016; Danquah 2017; De Cocker 2016; Donath 2015; Dutta 2014; Ellegast 2012; Gilson 2009; Gordon 2013; Graves 2015; Healy 2013; Healy 2016; Kress 2014; Li 2017; MacEwen 2017; Neuhaus 2014a; Pedersen 2013; Puig-Ribera 2015; Sandy 2016; Swartz 2014; Tobin 2016; Urda 2016).

Eight studies reported time spent in occupational sedentary behaviour, which we considered to be equivalent to time spent sitting at work (Carr 2015; Coffeng 2014; Gao 2015; Mailey 2016; Pickens 2016; Schuna 2014; Verweij 2012; van Berkel 2014).

Number of prolonged sitting bouts at work

Three studies reported number of prolonged sitting bouts at work (Evans 2012; Danquah 2017; Swartz 2014).

Total duration of prolonged sitting bouts at work

Six studies reported time spent in prolonged periods of sitting at work (Brakenridge 2016; Danquah 2017; Evans 2012; Healy 2013; Neuhaus 2014a; Priebe 2015).

Total time spent sitting, including sitting at and outside work

Eight studies reported total time spent sitting, including sitting at and outside work (Alkhajah 2012; Brakenridge 2016; De Cocker 2016; Dutta 2014; Ellegast 2012; Healy 2016; MacEwen 2017; Verweij 2012).
Time spent standing and stepping at work

Sixteen studies reported time spent standing at work (Alkhajah 2012; Brakenridge 2016; Chau 2014; Chau 2016; Danquah 2017; De Cocker 2016; Donath 2015; Gao 2015; Graves 2015; Healy 2013; Healy 2016; Li 2017; MacEwen 2017; Neuhaus 2014a; Swartz 2014; Tobin 2016). Eleven studies reported time spent stepping at work (Alkhajah 2012; Brakenridge 2016; Chau 2014; Chau 2016; Graves 2015; Healy 2013; Healy 2016; Li 2017; Neuhaus 2014a; Swartz 2014; Tobin 2016).

Energy expenditure

Only one study reported estimated energy expenditure based on information about sitting time at work (Pedersen 2013). They used 1.5 METs to represent energy expenditure of sitting and 2.3 METs to represent energy expenditure of quiet standing.

Work productivity

Three studies assessed work performance on a scale from 1 to 10 (Alkhajah 2012; Healy 2013; Neuhaus 2014a). One study, Carr 2015, also reported they had assessed work productivity, but the authors did not report the results.

Two studies assessed work engagement on a scale from 0 to 6 (Coffeng 2014; van Berkel 2014), using the Utrecht Work Engagement Scale, a questionnaire that measures three aspects of engagement: vigour (six items); dedication (five items); and absorption (six items).

One study, Puig-Ribera 2015, reported the percentage of lost work productivity in terms of Work Limitation Questionnaire Index (WLQ Index) Score. WLQ Index Score is a weighted sum of the scores from the WLQ scales. The Work Limitation Questionnaire consists of 25 items which require employees to rate their level of difficulty to perform 25 specific job demands in the last two weeks. The individual items form four scales: time management; physical demands; mental or interpersonal; and output demands scale.

Adverse events

Three studies reported musculoskeletal symptoms by anatomical regions (Alkhajah 2012; Healy 2013; Neuhaus 2014a). Two studies reported musculoskeletal discomfort or pain at three sites: lower back, upper back, and neck and shoulders (Gao 2015; Graves 2015). The first study, Gao 2015, used a scale ranging from 1 (very comfortable) to 5 (very uncomfortable); and in Graves 2015, a scale ranging from 0 (no discomfort) to 10 (extremely uncomfortable) was used. Another study, Carr 2015, also reported having measured musculoskeletal discomfort but they presented no respective data in their article. One study, Danquah 2017, reported musculoskeletal symptoms at all sites on the scale from 0 to 6.

Four studies assessed work engagement on a scale from 0 to 6 (Coffeng 2014; van Berkel 2014), using the Utrecht Work Engagement Scale, a questionnaire that measures three aspects of engagement: vigour (six items); dedication (five items); and absorption (six items).

One study, Puig-Ribera 2015, reported the percentage of lost work productivity in terms of Work Limitation Questionnaire Index (WLQ Index) Score. WLQ Index Score is a weighted sum of the scores from the WLQ scales. The Work Limitation Questionnaire consists of 25 items which require employees to rate their level of difficulty to perform 25 specific job demands in the last two weeks. The individual items form four scales: time management; physical demands; mental or interpersonal; and output demands scale.

Follow-up times

In six studies the longest follow-up was one month or less (Evans 2012; Healy 2013; Li 2017; Priebe 2015; Swartz 2014; Urda 2016), and in 20 studies the longest follow-up was between one and three months (Alkhajah 2012; Brakenridge 2016; Chau 2014; Chau 2016; Danquah 2017; De Cocker 2016; Donath 2015; Dutta 2014; Ellegast 2012; Gilson 2009; Gordon 2013; Graves 2015; Healy 2016; Kress 2014; MacEwen 2017; Mailey 2016; Neuhaus 2014a; Pickens 2016; Schuna 2014; Tobin 2016). We categorised all these as short-term follow-up.

The remaining eight studies followed participants between three and 12 months (Carr 2015; Coffeng 2014; Gao 2015; Pedersen 2013; Puig-Ribera 2015; Sandy 2016; van Berkel 2014; Verweij 2012), which we categorised as medium-term follow-up.

No studies had a follow-up longer than 12 months, which we defined as long-term follow-up.

Excluded studies

Of the 54 papers we assessed as full-text, 33 did not meet our inclusion criteria and we summarily excluded them. Thirteen studies were not RCTs or controlled before-and-after studies with concurrent controls. Five studies were not conducted in a workplace setting and another 15 studies did not report sitting time at work. See the Characteristics of excluded studies table for further details.

Risk of bias in included studies

Risk of bias varied considerably across the studies (Figure 2).
Figure 2. Risk of bias graph: review authors’ judgements about each risk of bias item presented as percentages across all included studies.

- Low risk of bias
- Unclear risk of bias
- High risk of bias

**Allocation**

Seven studies, Alkhajah 2012, Chau 2016, Gao 2015, Healy 2013, Kress 2014, Neuhaus 2014a, Pickens 2016, did not randomise participants and we judged these studies to be at high risk of bias for the domain of random sequence generation. Except for De Cocker 2016, Puig-Ribera 2015, and Tobin 2016, all the studies described the method of randomisation they had used, so we judged them as having a low risk of bias for the domain of sequence generation. Although these studies mentioned in their publication they conducted randomised trials (De Cocker 2016; Puig-Ribera 2015; Tobin 2016), they did not describe the method of randomisation and so we judged them to have an unclear risk of bias. One study, Donath 2015, used the minimisation method which is considered equivalent to randomisation (Chapter 8 of the Cochrane Handbook for Systematic Reviews of Interventions, Higgins 2011). Only nine studies reported concealing intervention versus control group allocation, so we judged these studies to be at low risk of bias (Brakenridge 2016; Carr 2015; Danquah 2017; Ellegaard 2012; Evans 2012; Li 2017; Mailey 2016; Schuna 2014; Swartz 2014). Eleven studies provided no information on allocation concealment, thus we judged these studies to be at unclear risk of bias (Coffeng 2014; De Cocker 2016; Donath 2015; Gilson 2009; Gordon 2013; MacEwen 2017; Priebe 2015; Puig-Ribera 2015; Sandy 2016; Tobin 2016; Uda 2016). Allocation was not concealed in the remaining studies (Alkhajah 2012; Chau 2014; Chau 2016; Dutta 2014; Gao 2015; Graves 2015; Healy 2013; Healy 2016; Kress 2014; Neuhaus 2014a; Pedersen 2013; Pickens 2016; van Berkel 2014; Verweij 2012) and thus we judged them to be at high risk of bias.

**Blinding**

In all but a single study (Verweij 2012), the blinding of participants to the interventions they were receiving was not done due to the nature and aims of interventions being self-evident, so we judged that these 33 studies had a high risk of bias in the performance bias domain. The single study, Verweij 2012, reported asking randomised occupational physicians not to reveal their allocation to participating employees who were their patients. With regard to outcome assessment, only three studies reported blinding of outcome assessor to group allocation and thus we judged them to have a low risk of bias (Danquah 2017; Evans 2012; Li 2017). One study, Healy 2013, reported that outcome assessors were not blinded to group allocation and we judged their study to have a high risk of bias. The remaining studies did not report on blinding of outcome assessors and thus we judged them to have an unclear risk of detection bias.

**Incomplete outcome data**

We judged 16 studies to have a high risk of bias due to incomplete outcome data (Chau 2016; De Cocker 2016; Donath 2015; Dutta 2014; Gao 2015; Gilson 2009; Kress 2014; Li 2017; MacEwen 2017; Mailey 2016; Neuhaus 2014a; Pickens 2016; Priebe 2015; Puig-Ribera 2015; Swartz 2014; Verweij 2012). One study, Dutta 2014, did not report 14% of working hours; the remaining studies lost more than 10% of participants during the follow-up period. We judged all the remaining 18 studies to have a low risk of bias for incomplete outcome data because of the following reasons. Three studies, Gordon 2013, Graves 2015, and van Berkel 2014, con-
ducted an intention-to-treat analysis. One study, Coffeng 2014, conducted multilevel analysis to account for missing data. Another, Chau 2014, reported that imputing values for missing covariate data did not influence the estimated adjusted effects of the intervention on the outcomes. Three studies, Brakenridge 2016, Danquah 2017, and Healy 2016, reported assessing sensitivity of results by multiple imputation using chained equations. Another three studies, Evans 2012, Healy 2013, and Tobin 2016, lost the same proportion of participants from both the intervention groups and the control groups, so we assumed that the missing data was unlikely to have had a significant impact on outcomes (Cochrane Handbook for Systematic Reviews of Interventions, section 8.13.2, Higgins 2011).

Selective reporting
We judged five studies to have a high risk of bias due to discordance between outcomes in available protocols and the ones reported in study results (De Cocker 2016; Evans 2012; Li 2017; Neuhaus 2014a; Schuna 2014). We judged the remaining 17 studies to have a low risk of bias as they reported results for all the outcome measures mentioned either in the protocol or in the methods section of studies where a protocol was not available (Alkhajah 2012; Chau 2014; Coffeng 2014; Donath 2015; Dutta 2014; Gao 2015; Gilson 2009; Gordon 2013; Healy 2013; Pedersen 2013; Puig-Ribera 2015; Schuna 2014; Swartz 2014; van Berkel 2014; Verweij 2012).

Other potential sources of bias
This domain had the following two parts of assessment, as decided a priori:

- validity of outcome measure;
- baseline comparability or imbalance for age, gender and occupation of study groups.

Eight studies assessed sitting time at work using questionnaires (Coffeng 2014; Gao 2015; Pedersen 2013; Pickens 2016; Priebe 2015; Sandy 2016; Verweij 2012; van Berkel 2014). Questionnaires are cost-effective and readily accessible to the majority of the population, but participants receiving the intervention might be aware of the goals and the purpose of the intervention and may, therefore, misreport outcomes (Healy 2011). In six studies (Coffeng 2014; Gao 2015; Priebe 2015; Sandy 2016; Verweij 2012; van Berkel 2014), the questionnaire used has not been tested for validity in assessing time spent sitting at work. Two studies, Pedersen 2013, and Pickens 2016 used the Occupational Sitting and Physical Activity Questionnaire (OSPAQ) which has moderate validity for assessing time spent sitting at work (Chau 2012). Another two studies, Gilson 2009, and Puig-Ribera 2015, assessed sitting time using a paper-based diary (log book). The validity and reliability of assessing sitting time using log-books has not been established. However, they are less dependent on long-term recall and therefore might provide a more accurate measurement of sitting time at work. In any case log data are subject to reporting bias, as it is not possible to determine whether the log has been filled in at the required intervals or if it was, for example, completed in whole on the final day of assessment (Clark 2009). In Graves 2015, sitting time at work was assessed with Ecological Momentary Assessment diaries. This is a valid, reliable, and feasible approach to assess physical activity and sedentary behaviour. The benefit of Ecological Momentary Assessment is its ability to collect data in real-time and real-world circumstances; hence there is no recall bias (Marszalek 2014).

Twenty-three studies assessed sitting time at work with an accelerometer-inclinometer (Alkhajah 2012; Brakenridge 2016; Carr 2015; Chau 2014; Chau 2016; Danquah 2017; De Cocker 2016; Donath 2015; Dutta 2014; Ellegast 2012; Evans 2012; Gordon 2013; Healy 2013; Healy 2016; Kress 2014; Li 2017; MacEwen 2017; Mailey 2016; Neuhaus 2014a; Schuna 2014; Swartz 2014; Tobin 2016; Urda 2016). Such device-based measurements also have some limitations, as outcomes may be affected by methodological decisions made before and after the data collection (e.g. type of accelerator, cut-off points, and non-wear time definitions) (Janssen 2015; Pedisi 2015). Self-reported sedentary time has shown to have low to moderate correlation with accelerometer-derived sedentary time, with improved validity when specific domains of sedentary time are recalled (e.g. time spent watching television, computer use, sitting at work; Healy 2011). We therefore judged six studies to have a high risk of bias based on validity of outcome measure (Coffeng 2014; Gao 2015; Priebe 2015; Sandy 2016; Verweij 2012; van Berkel 2014).

We judged two studies to have a high risk of other bias. In Alkhajah 2012, participants in the intervention group were academics involved in sedentary behaviour research, whilst participants in the control group had never been involved in sedentary behaviour or physical activity research. In Gao 2015, Gordon 2013, MacEwen 2017, Mailey 2016, and Pickens 2016, a significant difference was reported between the intervention group and the control group in baseline characteristics and thus we judged these studies to have a high risk of bias. Four studies did not report characteristics of participants at baseline and thus we judged them to have an unclear risk of bias (Priebe 2015; Puig-Ribera 2015; Sandy 2016; Urda 2016). We judged all other studies to have a low risk of other bias, as neither baselines nor outcome validity was questionable.

Overall Risk of Bias
Overall, we judged only three studies to have a low risk of bias (Carr 2015; Danquah 2017; Ellegast 2012). The remaining studies were judged to have a high risk of bias overall based on: inadequate randomisation (Alkhajah 2012; Chau 2016; Gao 2015; Healy 2013; Kress 2014; Neuhaus 2014a; Pickens 2016); allocation concealment (Alkhajah 2012; Chau 2014; Chau 2016; Dutta 2014; Gao 2015; Graves 2015; Healy 2013; Healy 2016; Kress 2014;
Neuhaus 2014a; Pedersen 2013; Pickens 2016; van Berkel 2014; Verweij 2012); blinding of outcome assessment (Healy 2013); incomplete outcome data (Chau 2016; De Cocker 2016; Donath 2015; Dutta 2014; Gao 2015; Gilson 2009; Kress 2014; Li 2017; MacEwen 2017; Mailey 2016; Neuhaus 2014a; Pickens 2016; Priebe 2015; Puig-Ribera 2015; Swartz 2014; Verweij 2012); selective reporting (De Cocker 2016; Evans 2012; Li 2017; Neuhaus 2014a; Schuna 2014); and other bias (Alkhajah 2012; Brakenridge 2016; Coffeng 2014; Gao 2015; Gordon 2013; MacEwen 2017; Mailey 2016; Pickens 2016; Sandy 2016; van Berkel 2014; Verweij 2012). See Figure 3 for a summary of our judgements about each risk of bias item for each included study.

Effects of interventions

See: Summary of findings for the main comparison Alternative desks and workstations compared to sit-desks for reducing sitting at work; Summary of findings 2 Workplace policy changes compared to no intervention or alternate intervention for reducing sitting at work; Summary of findings 3 Information, feedback, and/or counselling compared to information only or no intervention for reducing sitting at work; Summary of findings 4 Multi-component intervention compared to no intervention for reducing sitting at work

We present results using only outcomes for which data were available.

Physical changes in the workplace design and environment

**Sit-stand desk with or without information and counselling versus sit-desk**

**Outcome: sitting time**

**Time spent sitting at work: follow-up at short term**

Ten studies compared the effects of using a sit-stand desk with or without information and counselling to the effects of using a sit-desk (Chau 2014; Chau 2016; Dutta 2014; Gao 2015; Graves 2015; Healy 2013; Li 2017; MacEwen 2017; Neuhaus 2014a; Tobin 2016). The pooled analysis showed that the sit-stand desk with or without information and counselling intervention reduced sitting time at work by more than 100 minutes per eight-hour workday (95% CI −116 to −84, \( I^2 = 37\% \); Analysis 1.1). In a subgroup analysis, there was no difference in effectiveness between sit-stand desks with information and counselling and sit-stand desks only in reducing sitting time at work. In a subgroup analysis including only RCTs, (four studies, Graves 2015; Li 2017; MacEwen 2017; Tobin 2016), a sit-stand desk with information and counselling reduced sitting time at work on average by 105 minutes (95% CI −128 to −82, \( I^2 = 0\% \); Analysis 1.2). Data presented by one study, Sandy 2016, did not allow for calculation of time spent in sitting time at work and therefore we did not include the study in the quantitative synthesis. The prediction interval for sitting time ranged from −146 to −54 minutes a day, indicating that in 95% of cases the true effect of a new unique intervention will fall within these values.

**Time spent sitting at work: follow-up at medium-term**

At medium-term follow-up, two controlled before-and-after studies (Chau 2016; Gao 2015), that provided workers with sit-stand desks, reduced sitting time at work on average by 57 minutes per eight-hour workday (95% CI −99 to −15, \( I^2 = 0\% \)) compared to sit-desks (Analysis 1.3).

**Summary of findings 2**

**Total duration of sitting bouts lasting 30 minutes or more: follow-up at short-term**

Two controlled before-and-after studies containing three study arms measured the intervention effect on the total duration of sitting bouts lasting 30 minutes or more (Healy 2013; Neuhaus 2014a).

In Neuhaus 2014a, they compared the effects of using a sit-stand desk only with a sit-stand desk combined with counselling and with a sit-desk. In Healy 2013, they compared a sit-stand desk combined with counselling with a sit-desk. The pooled effect estimate combining sit-stand desk and sit-desk desk combined with counselling showed a reduction of 53 minutes, on average, per eight-hour workday (95% CI −79 to −26) in the total duration of sitting bouts lasting 30 minutes or more in the intervention group, with moderate heterogeneity (\( I^2 = 45\% \); Analysis 1.4). Analysis of the subgroup of interventions combining sit-stand desks with counselling resulted in a mean reduction of 63 minutes per eight-hour workday (95% CI −93 to −34), with moderate heterogeneity (\( I^2 = 31\% \); Analysis 1.4).

**Total time spent sitting, including sitting at and outside work: follow-up at short-term**

The pooled analysis of two studies (Alkhajah 2012; MacEwen 2017), which compared the effects of sit-stand desks and sit-desks on total sitting time, including sitting at work and outside work, at short-term follow-up showed a reduction of 82 minutes, on average, per day (95% CI −124 to −39, \( I^2 = 0\% \); Analysis 1.5).

**Outcome: standing and stepping time**

**Time spent standing at work: follow-up at short-term**

Nine studies reported time spent standing at work at short-term follow-up (Alkhajah 2012; Chau 2014; Chau 2016; Graves 2015; Healy 2013; Li 2017; MacEwen 2017; Neuhaus 2014a; Tobin 2016). The pooled analysis showed that sit-stand desks with or without information and counselling increased standing time at work on average by 89 minutes per eight-hour workday (95% CI
Time spent stepping at work: follow-up at short-term

In the pooled analysis of eight studies (Alkhajah 2012; Chau 2014; Chau 2016; Graves 2015; Healy 2013; Li 2017; Neuhaus 2014a; Tobin 2016), we found no significant difference between the effects of sit-stand desks and sit-desks on time spent stepping at work at short-term follow-up (MD = 1 minute per eight hour workday, 95% CI −4 to 3, I² = 0%; Analysis 1.8).

Time spent standing at work: follow-up at medium-term

At medium-term follow-up, two controlled before-and-after studies (Chau 2016; Gao 2015), found that providing workers with sit-stand desks increased standing time at work on average by 53 minutes per eight-hour workday (95% CI 17 to 90, I² = 0%) compared to sit-desks (Analysis 1.9).

Outcome: work performance

Self-reported work performance: follow-up at short-term

In three studies (Alkhajah 2012; Healy 2013; Neuhaus 2014a), interventions with sit-stand desks produced a non-significant pooled effect on work performance (on a scale from 1 to 10; MD 0.35 score points; 95% CI −0.1 to 0.8; Analysis 1.10). In these studies, work performance was assessed with a 10-item scale ranging from 1 to 10 relating to the past week, with higher values on the scale indicating better performance.

Number of sick days: follow-up at short-term

One study found no significant change in the proportion of employees having more than one sick day in the sit-stand desk group compared to sit-desk in the three months following the installation of sit-stand desks (risk ratio (RR) 2.2, 95% CI 0.9 to 5.2; Analysis 1.11; Alkhajah 2012).

Two studies assessed the proportion of people with more than one sick day in the last month at three months follow-up (Healy 2013; Neuhaus 2014a). We found no significant pooled effect of the introduction of sit-stand desks on the risk of having more than one sick day in the last month (RR 0.8, 95% CI 0.5 to 1.2). Accordingly, we found no significant effects for interventions that included information and counselling along with a sit-stand desk (RR 0.7, 95% CI 0.4 to 1.2) and for those that included sit-stand desks only (RR 0.9, 95% CI 0.4 to 2.1; Analysis 1.12).

Outcome: adverse events

Overall body pain

In one controlled before-and-after study, Neuhaus 2014a, one out of 13 participants in the sit-stand desk group withdrew from the trial because of overall body pain.

Musculoskeletal symptoms: follow-up at short-term

Three studies, Alkhajah 2012, Healy 2013, and Neuhaus 2014a, reported musculoskeletal symptoms, assessed using questions with a binary response scale (yes/no), by anatomic regions. We did not combine their results in a meta-analysis because of substantial heterogeneity in the results (I² = 98%).

Two studies found a lower prevalence of musculoskeletal symptoms among participants using sit-stand desks compared to those using sit-desks at three months follow-up (Alkhajah 2012; Neuhaus 2014a). In the study by Neuhaus 2014a, the magnitude of the effect was significantly larger (MD = −16.5, 95% CI −17.8 to −15.3) than in the study by Alkhajah 2012 (MD = −6, 95% CI −6.9 to −5.1).

In Healy 2013, a significant but relatively small increase was found in the percentage of participants with musculoskeletal symptoms in the sit-stand desk combined with counselling group (MD 4, 95% CI 2.6 to 5.5), while in Neuhaus 2014a, a slight decrease was found in the percentage of participants with musculoskeletal symptoms (MD = −11.5, 95% CI −12.6 to −10.5) in the sit-stand desk combined with counselling group compared to the sit-desk group at three-month follow-up.

In Graves 2015, a non-significant change was found in the ratings of musculoskeletal discomfort by participants using sit-stand desks compared to participants using sit-desk at short-term follow-up (MD = −0.5, 95% CI −1 to 0; Analysis 1.13). Participants rated
musculoskeletal discomfort or pain at three sites (lower back, upper back, and neck and shoulders) on a Likert scale ranging from 0 (no discomfort) to 10 (extremely uncomfortable).

Musculoskeletal symptoms: follow-up at medium-term

One study, Gao 2015, assessed perceived musculoskeletal comfort for different body parts (neck and shoulders, upper limbs, back, and lower limbs) rated at the end of a normal workday on a scale from 1 (very comfortable) to 5 (very uncomfortable). The study found a significant but relatively small change in musculoskeletal symptoms with a sit-stand desk compared to a sit-desk at six-month follow-up (MD −0.5, 95% CI −0.9 to −0.2; Analysis 1.14).

Standing desk versus sit-stand desk

Outcome: sitting time

Time spent sitting at work

One controlled before-and-after study, Kress 2014, found that using a standing desk reduced sitting time at work in their sample on average by 10 minutes per eight-hour workday (95% CI −62 to 43) at short-term follow-up (Analysis 2.1) and by 19 minutes per eight-hour workday (95% CI −64 to 26) at medium-term follow-up, but these effects were not statistically significant (Analysis 2.2). Data presented by another study, Pickens 2016, did not allow for calculation of time spent sitting at work and the study was therefore not included in the quantitative synthesis.

Active workstation versus sit-desk

Outcome: sitting time

Time spent sitting at work: follow-up at short-term

Treadmill desk combined with counselling versus sit-desk

One RCT, Schuna 2014, found that a treadmill desk combined with counselling reduced sitting time at work by 29 minutes on average per eight-hour workday (95% CI −55 to −2) compared to no intervention at short-term follow-up (Analysis 3.1).

Time spent in inactive sitting at work: follow-up at medium-term

Cycling desks + information and counselling versus information and counselling only

One RCT, Carr 2015, found a non-significant decrease in inactive sitting at work (MD −12 minutes per day, 95% CI −24 to 1) with a cycling desk combined with information and counselling compared to information and counselling only at medium-term follow-up (Analysis 3.2).

Outcome: work productivity

One RCT, Carr 2015, found no significant change in musculoskeletal discomfort over the past seven days and work productivity with a cycling desk combined with information and counselling compared to information and counselling only at medium-term follow-up. The study did not report any quantitative data for these outcomes.

Walking strategies versus no intervention

Outcome: sitting time

Time spent sitting at work: follow-up at short-term

A three-armed RCT, Gilson 2009, found a non-significant decrease in mean sitting time at work per day (MD −15 minutes per day, 95% CI −50 to 19) in route and incidental walking groups compared to a control group (Analysis 4.1).

Time spent sitting at work: follow-up at medium-term

A cluster-RCT, Puig-Ribera 2015, found a non-significant decrease in sitting time at work (MD −17 minutes per day, 95% CI −61 to 28) following a web-based intervention encouraging incidental walking and short walks during the working day compared to a control group at 21-week follow-up (Analysis 4.2).

Outcome: work productivity

Percentage of lost work productivity: follow-up at medium-term

One cluster-RCT, Puig-Ribera 2015, found walking strategies resulted in an average decrease in Work Limitation Questionnaire Index Score of −2.6% (95% CI −4 to −1.3) when compared to no intervention (Analysis 4.3).
Short break versus long break

**Time spent sitting at work: follow-up at short-term**

One RCT, Mailey 2016, reported that short breaks reduced time spent sitting at work by 40 minutes per eight-hour workday (95% CI −66 to −15) when compared to long breaks at short-term follow-up (Analysis 5.1).

Information and counselling

**Information, counselling, and feedback versus no intervention**

Outcome: sitting time

Two RCTs compared the effects of information and feedback to no intervention on time spent sitting a work at short-term follow-up (De Cocker 2016; Gordon 2013). The pooled effect size for information, feedback, reminder, or all of the above was not significantly different from no intervention (MD −19 minutes per eight-hour workday, 95% CI −57 to 19; I² = 0%; Analysis 6.1).

**Time spent sitting at work: follow-up at medium-term**

The pooled analysis of two RCTs comparing counselling to no intervention, Coffeng 2014, and Verweij 2012, showed that counselling reduced sitting time at work on average by 28 minutes per eight-hour workday (95% CI −51 to −5; I² = 0%; Analysis 6.2).

**Total time spent sitting, including sitting at and outside work: follow-up at short-term**

One RCT, De Cocker 2016, found a non-significant decrease in total sitting time with guideline-based counselling by an occupational physician compared to usual care by an occupational physician (MD −20 minutes per day, 95% CI −85 to 45; Analysis 6.3).

**Outcome: standing time at work**

One RCT, De Cocker 2016, found a non-significant effect of information and feedback compared to no intervention on time spent standing at work at short-term follow-up (MD 10 minutes per eight-hour workday, 95% CI −17 to 38; Analysis 6.5).

**Outcome: work engagement**

One RCT, Coffeng 2014, found a non-significant difference in work engagement (MD 0.1 score points, 95% CI −0.1 to 0.3; on a scale of 0 to 6) at medium-term follow-up (Analysis 6.6).

**Prompts combined with information versus information alone**

Outcome: sitting time

Two RCTs compared the effects of computer prompts combined with information to information only on time spent sitting at work (Donath 2015; Urda 2016). The pooled effect size for the computer prompts combined with information compared to information alone was not significant (−10 minutes per eight-hour workday, 95% CI −45 to 24; I² = 0%) (Analysis 7.1).

**Time spent sitting at work: follow-up at short-term**

One RCT, Pedersen 2013, reported a mean decrease in sitting time at work of 55 minutes per eight-hour workday (95% CI −96 to −14) when computer prompting combined with information was compared to information alone (Analysis 7.2).
Number of sitting bouts lasting 30 minutes or more: follow-up at short-term

One RCT, Evans 2012, found a significant but small decrease of on average 1.1 sitting bouts lasting 30 minutes or more per day (95% CI −1.9 to −0.3) when computer prompting combined with information was compared to information alone (Analysis 7.3).

Total duration of sitting bouts lasting 30 minutes or more: follow-up at short-term

One RCT, Evans 2012, also found a reduction of on average 74 minutes per day in the total duration of sitting bouts lasting 30 minutes or more (95% CI −124 to −24) when computer prompts combined with information was compared to information alone (Analysis 7.4).

Total time spent sitting, including sitting at and outside work: follow-up at short-term

One RCT, Evans 2012, found a non-significant decrease in total time spent sitting, including sitting at and outside work, with information and feedback compared to no intervention at short-term follow-up (MD −18 minutes per day, 95% CI −53 to 17) (Analysis 7.5).

Outcome: standing time at work

Time spent standing at work: follow-up at short-term

One RCT, Swartz 2014, found that employees who received computer prompts to step, sat on average 14 minutes per eight-hour workday more (95% CI 10 to 19) than employees who received computer prompts to stand (Analysis 8.1).

Number of sitting bouts lasting 30 minutes or more: follow-up at short-term

In the same study, Swartz 2014, the number of sitting events lasting 30 minutes or more was on average 0.4 (95% CI 0.3 to 0.5) higher among the employees in the step group than among the employees in the stand group (Analysis 8.2).

Outcome: standing and stepping time

Time spent standing and stepping at work: follow-up at short-term

One RCT, Swartz 2014, found that employees who received computer prompts to step stood on average 12 minutes less (95% CI −15 to −8; Analysis 8.3) and stepped on average 7 minutes more (95% CI 5 to 8; Analysis 8.4) compared to employees who received computer prompts to stand.

Highly personalised information versus less personalised information

Total duration of sitting bouts lasting 30 minutes or more: follow-up at short-term

One RCT, Priebe 2015, found a non-significant increase in the total duration of sitting bouts lasting 30 minutes or more at short-term follow-up (MD 14 minutes per eight-hour workday, 95% CI −37 to 65; Analysis 9.1).
Mindfulness training versus no intervention

Outcome: sitting time

Time spent sitting at work: follow-up at medium-term
One RCT, van Berkel 2014, found a non-significant reduction in sitting time at work with mindfulness training compared to no intervention at medium-term follow-up (MD −23 minutes per day, 95% CI −63 to 17; Analysis 10.1).

Outcome: work engagement
One study, van Berkel 2014, reported no significant difference in work engagement (on a scale of 0 to 6) at medium-term follow-up (0.2 score points; 95% CI −0.1 to 0.5; Analysis 10.2). The authors assessed work engagement using the Utrecht Work Engagement Scale, which is a self-reported questionnaire that measures three aspects of engagement: vigour, dedication and absorption.

Activity tracker combined with organisational support versus organisational support only

Time spent sitting at work: follow-up at short-term
One RCT, Brakenridge 2016, found a non-significant difference in the effectiveness of an activity tracker combined with organisational support and organisational support only in reducing time spent sitting at work at short-term follow-up (MD −6.60 minutes per eight-hour workday, 95% CI −35 to 22; Analysis 11.1).

Time spent sitting at work: follow-up at medium-term
One RCT, Brakenridge 2016, found a non-significant difference in the effectiveness of an activity tracker combined with organisational support and organisational support only in reducing time spent sitting at work at medium-term follow-up (MD −4.40 minutes per eight-hour workday, 95% CI −33 to 22; Analysis 11.2).

Total duration of sitting bouts lasting 30 minutes or more: follow-up at short-term
One RCT, Brakenridge 2016, found a non-significant increase in the duration of sitting bouts lasting 30 minutes or more at short-term follow-up with an activity tracker combined with organisational support compared to organisational support only (MD 11 minutes per eight-hour workday, 95% CI −28 to 50; Analysis 11.3).

Total duration of sitting bouts lasting 30 minutes or more: follow-up at medium-term
One RCT, Brakenridge 2016, found a non-significant difference in the effectiveness of an activity tracker combined with organisational support and organisational support only in reducing duration of sitting bouts lasting 30 minutes or more at medium-term follow-up (MD −1 minute per eight-hour workday, 95% CI −51 to 48; Analysis 11.4).

Total time spent sitting, including sitting at and outside work: follow-up at short-term
One RCT, Brakenridge 2016, found a non-significant difference in the effectiveness of an activity tracker combined with organisational support and organisational support only in reducing total time spent sitting, including sitting at and outside work, at short-term follow-up (MD 2 minutes per eight-hour workday, 95% CI −42 to 46; Analysis 11.5).

Total time spent sitting, including sitting at and outside work: follow-up at medium-term
One RCT, Brakenridge 2016, found a non-significant decrease in total time spent sitting, including sitting at and outside work, at medium-term follow-up with an activity tracker combined with organisational support compared to organisational support only (MD −8 minutes per eight-hour workday, 95% CI −57 to 40; Analysis 11.6).

Outcome: standing and stepping time

Time spent standing and stepping at work: follow-up at short-term
One RCT, Brakenridge 2016, found a non-significant change in time spent standing (MD 3 minutes per eight-hour workday, 95% CI −20 to 26 minutes per eight-hour workday; Analysis 11.7) and stepping at work (MD 4 minutes per eight-hour workday, 95% CI −6 to 14 minutes per eight-hour workday; Analysis 11.8) with an activity tracker combined with organisational support compared to organisational support only at short-term follow-up.

Time spent standing and stepping at work: follow-up at medium-term
One RCT, Brakenridge 2016, found a non-significant change in time spent standing (MD −12 minutes per eight-hour workday, 95% CI −45 to 20 minutes per eight-hour workday; Analysis 11.9) and stepping at work (MD 8 minutes per eight-hour workday, 95% CI −4 to 19 minutes per eight-hour workday; Analysis...
Multi-component intervention versus no intervention

Outcome: sitting time

Time spent sitting at work: follow-up at short-term
Three RCTs reported effects on time spent sitting at work at short-term follow-up (Ellegast 2012; Danquah 2017; Healy 2016). The pooled analysis of two studies (Ellegast 2012; Healy 2016), showed a significant reduction of on average 101 minutes per eight-hour workday (95% CI −117.27 to −84, I² =0%; Analysis 12.1) in time spent sitting at work at short-term follow-up. However, the third study, Danquah 2017, reported a much smaller reduction in sitting of on average 48 minutes per eight-hour workday (95% CI −62 to −34). Therefore, we did not pool this study with the other two studies comparing the effect of multi-component intervention versus no intervention, due to substantial heterogeneity (I² = 92%).

Time spent sitting at work: follow-up at medium-term
The pooled analysis of two RCTs (Coffeng 2014; Healy 2016), showed a significant decrease of on average 46 minutes per eight-hour workday in workplace sitting (95% CI −63 to −29, I² = 0%) following multi-component intervention compared to no intervention at medium-term follow-up (Analysis 12.2).

Number of sitting bouts lasting 30 minutes or more: follow-up at short-term
One RCT, Danquah 2017, found a small decrease in the number of sitting bouts lasting 30 minutes or more with multi-component intervention compared to no intervention at short-term follow-up (MD −0.4 bouts per day, 95% CI −0.7 to −0.12; Analysis 12.3).

Total duration of sitting bouts lasting 30 minutes or more: follow-up at short-term
One RCT, Healy 2016, found a decrease of 73 minutes, on average, per eight-hour workday (95% CI −94 to −51) in the total duration of sitting bouts lasting 30 minutes or more following multi-component intervention compared to no intervention at short-term follow-up. However, in the study by Danquah 2017, a much smaller decrease was found in the total duration of sitting bouts lasting 30 minutes or more of on average 16 minutes per eight-hour workday (95% CI −31 to −1) following multi-component intervention. Therefore, we did not pool the results of these two studies due to substantial heterogeneity (Analysis 12.4, I² = 95%). Total duration of sitting bouts lasting 30 minutes or more: follow-up at medium-term
One RCT, Healy 2016, reported a non-significant decrease of on average 18 minutes per eight-hour workday (95% CI −46 to 10) in the total duration of sitting bouts lasting 30 minutes or more at medium-term follow-up (Analysis 12.5).

Outcome: standing and stepping time

Time spent standing and stepping at work: follow-up at short-term
Two RCTs reported effects on time spent standing at work at short-term follow-up (Danquah 2017; Healy 2016). In Healy 2016, an increase was reported of on average 95 minutes per eight-hour workday (95% CI 79 to 112) in time spent standing at work with multi-component intervention compared to no intervention (Analysis 12.8). Danquah 2017, however, reported a significantly smaller increase of 43 minutes, on average, per eight-hour workday (95% CI 30 to 56; Analysis 12.8). We did not pool the results of these two studies due to high heterogeneity (I² = 96%).

Outcome: sitting and standing intervention combined

Total time spent sitting, including sitting at and outside work: follow-up at short-term
Two RCTs reported total time spent sitting, including sitting at and outside work, at short-term follow-up (Ellegast 2012; Healy 2016). The pooled analysis showed a significant reduction of on average 73 minutes per day (95% CI −92 to −54) in total time spent sitting, including sitting at and outside work with multi-component intervention compared to no intervention (Analysis 12.6).

Total time spent sitting, including sitting at and outside work: follow-up at medium-term
One RCT, Healy 2016, reported a reduction of on average 36 minutes per day (95% CI −62 to −11) in total time spent sitting, including sitting at and outside work, at medium-term follow-up (Analysis 12.7).

Total time spent standing, including sitting at and outside work: follow-up at short-term
One RCT, Healy 2016, reported a significant decrease of on average 46 minutes per eight-hour workday (95% CI −63 to −29, I² = 0%) following multi-component intervention compared to no intervention at short-term follow-up (Analysis 12.9).
Time spent standing and stepping at work: follow-up at medium-term

One RCT, Healy 2016, reported an average increase of 43 minutes per eight-hour workday (95% CI 26 to 60; Analysis 12.10) in standing time, whilst they found no significant change in stepping time at work (MD 0 minutes per eight-hour workday, 95% CI −5 to 4; Analysis 12.11) at medium-term follow-up.

Outcome: work engagement

One study, Coffeng 2014, reported no change in work engagement scale score (MD 0 points, 95% CI −0.1 to 0.1, on a scale from 0 to 6) following multi-component intervention compared to no intervention at medium-term follow-up (Analysis 12.12).

Outcome: adverse events

Musculoskeletal symptoms: follow-up at short-term

One study, Danquah 2017, reported no change in musculoskeletal symptom score (MD −0.2 points, 95% CI −0.32 to −0.02, on a scale from 0 to 6) following multi-component intervention compared to no intervention at short-term follow-up (Analysis 12.13).
## ADDITIONAL SUMMARY OF FINDINGS

**Workplace policy changes compared to no intervention for reducing sitting at work**

**Patient or population:** employees who sit at work  
**Setting:** workplace  
**Intervention:** policy changes  
**Comparison:** no intervention

DISCUSSION

Summary of main results
We identified 34 studies which evaluated interventions for reducing sitting at work. These studies investigated physical workplace changes in workplace design and environment, workplace policy changes, information and counselling, and multi-component interventions for reducing sitting at work.

Physical workplace changes
According to ten studies, providing workers with sit-stand desks either alone or in combination with information and counselling reduces workplace sitting at short-term by on average 100 minutes per eight-hour workday (95% CI −116 to −84, low-quality evidence) compared to sit-desks. This finding shows that sit-stand desk interventions may contribute to achieving the two to four hours of standing at work promoted by a group of experts, in the short term (Buckley 2015). The prediction interval for sitting time at work resulting from interventions comparing sit-stand desks to sit-desks ranges from −146 to −54, indicating that in 95% of cases the effect a new unique intervention will fall within these values. It is important to know which activity replaced sitting with the implementation of intervention. The sit-stand desk intervention seems to replace sitting primarily with standing at short-term follow-up (MD 89 minutes, 95% CI 76 to 102). The effectiveness of sit-stand desk seems to decrease with the length of follow up, with two studies showing an average reduction of 57 minutes per day (95% CI −99 to −15) at medium-term follow-up. In two studies that had a follow-up at short-term, providing workers with sit-stand desks reduced the total amount of time spent in bouts of prolonged sitting by 53 minutes a day (95% CI −79 to −26, very low-quality evidence). Similarly, total sitting time (including sitting at and outside work) also decreased at short-term follow-up on average by 82 minutes per day (95% CI −124 to −39, two studies). A single study found a non-significant difference between standing desks and sit-stand desks in their effects on reducing the total amount of time spent in bouts of prolonged sitting. The effects of active workstations, such as treadmill desks or cycling desks, on sitting time were unclear or inconsistent.

Policies to change organisation of work
One study showed that implementing walking strategies had no significant effect on workplace sitting time at short-term (MD −15 minutes per day, 95% CI −50 to 19, low-quality evidence) and medium-term follow-up (MD −17 minutes per day, 95% CI −61 to 28). Furthermore, a single study found that short breaks (one to two minutes every half hour) reduced time spent sitting at work on average by 40 minutes per day (95% CI 66 to 15, low-quality evidence) more than long breaks (two 15-minute breaks per workday) at short-term follow-up.

Information and counselling
The pooled effect size from two studies which evaluated provision of information and feedback found a non-significant reduction in time spent sitting at work at short-term follow-up (MD −19 minutes per day, 95% CI −57 to 19, low-quality evidence). A pooled analysis of two studies comparing counselling to no intervention, showed a significant reduction in time spent sitting at work at medium-term follow-up (MD −28 minutes per day, 95% CI −51 to −5, low-quality evidence). Computer prompting led to a nonsignificant reduction in sitting time at work in the short term (MD −10 minutes per day, 95% CI −45 to 24, 2 studies, low-quality evidence). However, their effect at medium-term follow-up was significant (MD −55 minutes per day, 95% CI −96 to −15, one study). Furthermore, computer prompting resulted in a significant decrease in the average number (−1.1, 95% CI −1.9 to −0.3, one study) and duration (MD -74 minutes per day, 95% CI −124 to −24) of sitting bouts lasting 30 minutes or more. A single study found that, in the short term, employees receiving computer prompts to stand on average 14 minutes more per eight-hour workday (95% CI 10 to 19) than employees receiving computer prompts to stand. One study found no significant added benefit of providing highly personalised information compared to less personalised information in terms of reducing sitting time at work. A single study did not find a significant change in workplace sitting time at medium-term follow-up with mindfulness training (MD −16 minutes, 95% CI −45 to 12, low-quality evidence). Similarly, a single study found no significant effects of activity trackers on reducing sitting at work in short and medium terms.

Interventions from multiple categories
Multi-component interventions consisting of physical workplace changes, workplace policy changes, and informational components resulted in significant reductions of time spent sitting at work (three studies, very low-quality evidence) and time spent in prolonged sitting bouts (two studies, very low-quality evidence) in the short term. However, there was significant heterogeneity in effect sizes between different studies. At medium-term follow-up, the pooled effects of two studies showed a reduction of 46 minutes, on average, per eight-hour workday (95% CI −63 to −29) with multi-component intervention.

Overall completeness and applicability of evidence
In total, we included 34 studies assessing various kinds of interventions for reducing time spent sitting at work. Most studies assessed the effectiveness of sit-stand desks, and the results of our review largely concern this particular intervention. There are no RCTs or controlled before-and-after studies that have specifically
assessed the effects of standing meetings or walking meetings to reduce sitting at work.

The included studies are all from Australia, Europe, Canada, and the USA. We do not find any studies from other countries or continents. None of the included studies had been conducted in low- and middle-income countries. This potentially limits the generalisability of the findings of this review beyond the settings in which the included studies have been conducted. This is partly because work environments and normal practices vary greatly across the globe, and the acceptability and feasibility of workplace interventions pertaining to sitting at work may differ accordingly. Since obesity and other lifestyle-related diseases are common in high-income countries, it is not surprising that most studies were from such countries. However, since these diseases are now becoming increasingly prevalent in other countries, for example, in some parts of Asia (Tan 2011; Wang 2011), it would be important to test the effectiveness of these interventions among office employees in a more diverse range of countries.

Almost all studies included in this Cochrane Review have used only short-term follow-up. There are no studies with a follow-up period longer than one year. It is important to demonstrate that behaviour change from sitting to a more active behaviour is sustainable in the long term. The cost of interventions, such as implementation of sit-stand desks, may be considerable; but if the effects can be sustained in the long-term, potential benefits are more likely to outweigh the costs.

The population of participants in the included studies consists of office workers of academic institutions, a government agency, a police organisation, and private organisations. We believe that the overall population is largely representative of office workers who spend a large part of their working time sitting and who are in need of interventions to reduce their workplace sitting time.

Although individually focused interventions, such as sit-stand desks, seem to be very popular, they are considerably more expensive than standard desks and so their use may not be feasible in many workplaces with limited financial resources. In some settings, standing meetings may be an alternative, low-cost option for reducing sitting time at work (Atkinson 2014). Motivational posters or prompting to stand up or engage in light- to moderate-intensity physical activity, or placing printers or dust-bins away from desks, could also be feasible low-cost interventions for larger groups of employees. There is some evidence of health benefits available for breaking up sitting time with intermittent brief bouts of light-intensity or moderate-intensity physical activity (Bailey 2015; Larsen 2014) but, as for now, no definite conclusions can be drawn about applicability of such findings to workplaces. There is a need for evaluating the effectiveness of low-cost interventions that would enable workers to break up sitting time by engaging in brief bouts of physical activity. Only some of the included studies assessed outcomes like standing or stepping to identify where the sitting time was reallocated. It would be important to assess this in future studies, as reallocation of time spent sitting at work to walking or other physical activities would potentially be a more healthy substitute than reallocation to standing.

Quality of the evidence

Even though 26 of 34 studies included in this Cochrane Review are RCTs or cluster-RCTs, we considered the majority of them to be at high risk of bias and therefore the quality of evidence they yield is low to very low. With complex interventions in the occupational health setting, the random allocation and its concealment is known to be more difficult than in clinical trials. Nevertheless, nine of the included studies managed to achieve it. Unless sample size is large enough, random allocation does not distribute the potential confounders equally across groups; therefore, randomisation is not very effective in studies as small as those included in our review. Further, the self-evident nature of the interventions makes it very difficult to blind personnel and participants.

Risk of bias for device-based measures of sitting time by accelerometer-inclinometer differs from self-reported sitting time. Participants may be aware of the goals of intervention and overestimate or underestimate sitting time, if it is assessed by self-reports. Using accelerometer-inclinometers may make it less likely for participants to interfere with outcome measurement. Consequently the use of device-measured sedentary behaviour has been recommended for intervention trials (Pedisi 2015). Two studies are not RCTs as stated a priori in their publication, because they randomised only two groups (Alkhajah 2012; Neuhaus 2014a). The trial authors described them as quasi-RCTs. The risk of baseline differences is much higher for such studies with only two clusters, so we categorised these two studies as controlled before-and-after studies, rather than RCTs. We addressed the baseline imbalances for both studies in our 'Risk of bias' assessment. Although studies performed poorly on the allocation concealment and blinding of participants and personnel domains, most studies assessed the outcomes in a way that we judged to have a low risk of bias. Taking all this into consideration, we rated the overall quality of the evidence as low to very low.

Potential biases in the review process

We did not exclude articles published in languages other than English. In this way, we avoided language bias in our review. We could not assess the robustness of our results, as there were not enough studies with a low risk of bias to perform a meaningful sensitivity analysis.

To avoid publication bias, we searched sources of grey literature and unpublished studies and data. We noted no obvious asymmetry (which would indicate publication bias) in the funnel plots of studies comparing sit-stand desks with or without information and counselling with sit-desks for time spent sitting at work as an outcome (Figure 4). For other comparisons and outcomes, there
were too few studies per outcome (less than 10 studies) to assess publication bias using funnel plots. However, the fact that most included studies were small and all reported positive outcomes is indicative that there may be publication bias in this area. If more studies are included in a future update of this review, we will assess the extent of publication bias by means of funnel plots and Egger’s test (Egger 1997).

Figure 4. Funnel plot of comparison: 1 Sit-stand desk with or without information and counselling versus sit-desk, outcome: 1.1 Mean difference in time spent sitting at work: short-term follow-up.

Agreements and disagreements with other studies or reviews

Recently, several systematic reviews have been published on interventions for reducing sedentary behaviour (Commissaris 2016; Gardner 2015a; Martin 2015; Prince 2014). Two of these assessed the effectiveness of interventions for reducing sedentary behaviour in adults at the workplace as well as in other settings; they included 51 studies (Martin 2015), and 65 studies (Prince 2014). Both reviews concluded that sedentary behaviour interventions in adults may be effective for reducing sedentary behaviour. A recent systematic review by Commissaris 2016, containing 40 studies, assessed the effectiveness of workplace interventions to change employees’ sedentary behaviour or physical activity, or both. This systematic review found strong evidence for a decrease in sedentary behaviour with the use of alternative desks, and this differs considerably from our finding of very-low to low-quality evidence for alternative desks. Another recent systematic review with 26 included studies,
Gardner 2015a, looked into the behaviour change strategies adopted by sedentary behaviour interventions using the Behaviour Change Wheel. It found that using more techniques made the interventions more promising in terms of their effectiveness. The most frequently observed behaviour change techniques were: setting behavioural goals, providing social support, and environmental interventions. In Gardner 2015a, they found two workplace interventions to be promising: education and environmental interventions. Only the finding about the latter type of interventions is in line with the findings of our review.

The differences in energy expenditure between sitting and standing seem to be minor. In Mansoubi 2015, it was found that sitting typing tasks resulted in energy expenditure of 1.45 METs (standard deviation (SD) 0.32), whereas the energy cost of standing equated to 1.59 METs (SD 0.37). By contrast, there was a considerable difference between energy costs of sitting and physical activity; for example, walking MET values increased incrementally with speed from 2.17 METs (SD 0.5) at 0.2 miles/hour to 3.22 METs (SD 0.69) at 1.6 miles/hour. It is therefore clear that the use of more dynamic workstations has the potential to considerably increase energy costs. For example, energy expenditure of using a desk-bike type workstation at light intensity reaches 2.4 METs (Botter 2015). Mansoubi 2015, in line with this, questions if the health benefits of reduced sedentary behaviour are primarily driven by increases in energy expenditure that accompany the transition to light activity (e.g. cycling), differences in postural allocation (e.g. standing), or a combination of both (e.g. walking and cycling). This should be further investigated, to inform future interventions. Although obesity in employees might incur a significant loss for the workplace (Shrestha 2016), aiming to reduce obesity or overweight by standing up at work may, however, not be pragmatic. One study found only a marginally higher additional metabolic cost for quiet standing compared to sitting (Júdice 2015b). In theory, if an average man and woman spent 50% of an eight-hour workday standing, they would spend approximately an additional 20 kilocalories (kcal) and 12 kcal, respectively. Our findings show that after three months, a sit-stand desk combined with counselling increased time spent standing on average by 89 minutes (95% CI 76 to 102), so the additional energy expenditure that can be expected from standing in such interventions is negligible. In accordance with our finding, the authors of a longitudinal study suggested that increasing occupational standing time may not be sufficient to prevent the development of overweight, obesity, impaired glucose tolerance, and type 2 diabetes (Chaput 2015). One study has suggested that higher amounts of time spent standing may be associated with reduced risk of all-cause and cardiovascular-disease mortality (Katzmarzyk 2014). Given that mortality rates decline at higher levels of standing, regardless of insignificant increase in energy expenditure, it may be that standing is generally a healthier behaviour than sitting. However, promoting sustained standing over longer periods of time also does not seem a reasonable solution; for example, Andersen 2007, reported increased musculoskeletal symptoms associated with prolonged standing. Coenen and colleagues have mentioned that an intervention with increased standing and reduced sitting was less effective for people with low back pain than those without low back pain (Coenen 2015). It is not yet known at which amount of standing we may expect adverse health effects, but it is possible that promoting four hours of standing per day during work hours could have negative consequences for some population groups. For instance, elderly workers complain when performing standing work, even if it constitutes less than 50% of their working time (Graf 2015). Pedišič and colleagues have suggested that exploring the effectiveness of interventions promoting an optimal balance between physical activity, quiet standing, sedentary behaviour, and sleep may be an important avenue for future research (Pedišič 2017).
work, but significant heterogeneity in their effects across studies prevent estimation of a pooled effect size.

Implications for research

Regarding physical changes of the workplace design and environment, we need studies on sit-stand desks with larger sample sizes and longer duration of follow-up and more studies testing the effectiveness of active workstations. To prevent possible contamination, we recommend randomising employees using a cluster-randomised design with at least two intervention sites and two control sites but preferably many more, to minimise confounding by workplace-specific variables (EPOC). Even when employees are not explicitly told which group they are in, true blinding is not possible as intervention activities will be noticeable at work sites (McEachan 2011). We recommend conducting trials aimed at reducing sitting at work in low- and middle-income countries, where the burden of non-communicable diseases is also increasing.

Regarding policies to change the organisation of work, there is a need to conduct trials evaluating low-cost interventions (e.g. standing meetings or walking meetings, posters or prompts for standing, printers or dust-bins placed away from the workstation), as they might be the only feasible options in settings with limited financial resources. To develop more effective interventions, it might be important to first better understand the ideas that workers and employers have about health effects of excessive sitting and means to reduce it. There is qualitative research on this topic available that should be summarised in a systematic review.

Future studies should consider measuring the time spent sitting using wearable devices, because of their superior measurement properties compared to self-reports. Thigh-mounted accelerometer-inclinometers may be useful for this purpose, because the thigh changes its angle when shifting from sitting to standing (Janssen 2015). We do not recommend only employing self-reported measures as their validity may not be adequate for intervention trials (Aadahl 2003; Lagerstedt-Olsen 2014). Moreover, participants receiving the intervention are aware of the goals set and the intention of the intervention, and are therefore susceptible to recall bias when reporting their sitting time (Rzewnicki 2003; Shephard 2003). Furthermore, if the intervention is found to reduce sitting, future studies should try to examine what behaviour replaces sitting (e.g. standing, light-intensity physical activity, or moderate-to vigorous-intensity physical activity). Mansoubi and colleagues argued that reducing sitting time at work might result in more sitting during leisure (Mansoubi 2016). However, a recent systematic review found that interventions aimed at reducing sitting at work also reduced sitting during leisure time (Shrestha 2018). Hence, it is important that workplace intervention studies assess time spent sitting not only in the work domain but also, if possible, in non-occupational domains.

We recommend including outcome measures that will be of interest to employers, such as valid and reliable measures of productivity, job stress, absenteeism, and cardio-metabolic health. Future studies should also consider including cost-effectiveness analyses to help stakeholders and decision makers determine whether the cost of interventions to reduce sitting at work is justified by improvements in health and work-related outcomes.

Where applicable, the effect should be statistically adjusted for the clustering effect. The overall sample size and the number of clusters should be taken into account when recruiting participants, in order to calculate the required sample size for achieving adequate statistical power.

The ongoing studies that we identified study effectiveness of sit-stand desks, treadmill desks, cycle desks, walking strategies, computer prompts, provision of information, and counselling. There are still no workplace RCTs evaluating other types of interventions, such as sitting diaries, stepping devices and assessing specifically standing meetings or walking meetings.

Two ongoing studies have been designed according to our recommendations (Dunstan 2014; O’Connell 2015). Both studies are cluster-RCTs and will have at least two intervention and two control sites. These studies have planned to assess the effectiveness of sit-stand or height adjustable desks. Both studies have planned to measure sitting at work with an accelerometer-inclinometer.

Acknowledgements

We thank Jani Ruotsalainen, Managing Editor of the Cochrane Work Group, for providing administrative and logistical support for the conduct of the current review; and Kaisa Neuvonen, Information Specialist of the Cochrane Work Group, for developing the search strategies; and Heikki Laitinen for executing the search procedure.

We would also like to thank the Cochrane Work Group’s Editors, Esa-Pekka Takala and Anneli Oja järvi; and external peer reviewers, Kimi Sawada, Kristel King, Rintaro Mori and Hidde van der Ploeg, for their comments. We thank Joey Kwong, Elizabeth Royle, Jessica Sharp and Jani Ruotsalainen for copy editing the text.

We also wish to thank Suresh Kumar, Chukwudi P Nwankwo and Soumyadeep Bhaumik for their contribution to the previous version of this review.

### Characteristics of included studies  
**Alkhajah 2012**

| Methods | Non-random allocation by clusters: CBA  
Single-blind  
Study duration: 3 months  
Dropout: 9%  
**Location:** Australia  
**Recruitment:** control group participants were recruited from locations separated from the intervention group participants by at least 1 building level |
| --- | --- |
| Participants | **Population:** employees in public health research centres within 2 academic institutions, aged 20-65 years  
**Intervention group:** 18 participants  
**Control group:** 12 participants  
**Demographics:**  
BMI: intervention group 22.6 (SD 2.6) kg/m², control group 21.5 (SD 2.6) kg/m² |
| Interventions | **Duration:** 3 months  
**Intervention:** sit-stand desk  
**Control:** sit-desk |
| Outcomes | **Outcome name, measurement time/tool (units of measurement)**  
- Changes in sitting/standing/stepping time (minutes/8-hour workday) measured at 1 week and 3 months. Transitions in positions measured by activPAL3 accelerometer-inclinometer and a self-administered questionnaire  
- Weight (kg), waist circumference (cm), hip circumference (cm), fat free mass (kg), fat mass (kg), fasting blood lipids (Total cholesterol/HDL/Triglycerides) (mmol/L) and glucose (mmol/L) at 1 week and 3 months  
- Self-reported health- and work-related outcomes  
  - Musculoskeletal symptoms by anatomical regions  
  - Other health symptoms: eye strain, headaches, digestion problems, trouble walking, trouble sleeping, fatigue (scale 1-5)  
  - Work-related outcomes: ≥ 1 day off sick (last 3 months), work performance (scale 1-10) |
| Notes | This study was funded by a University of Queensland Major Equipment and Infrastructure grant. Alkhajah was supported by a United Arab Emirates Ministry of Higher Education and Scientific Research Scholarship; Reeves was supported by a National Health and Medical Research Council (NHMRC) Early Career Fellowship; Eakin was supported by an NHMRC Senior Research Fellowship; Owen was supported by an NHMRC Senior Principal Research Fellowship; and Healy was supported by an NHMRC Early Career Fellowship. ### Alkhajah 2012 (Continued)

<table>
<thead>
<tr>
<th>Bias Category</th>
<th>Risk Level</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Random sequence generation (selection bias)</td>
<td>High risk</td>
<td>Randomisation was not done as participants in intervention and control groups were selected from different building locations</td>
</tr>
<tr>
<td>Allocation concealment (selection bias)</td>
<td>High risk</td>
<td>Intervention and control groups were selected from two separate locations. However no information on allocation concealment</td>
</tr>
<tr>
<td>Blinding of participants and personnel (performance bias)</td>
<td>High risk</td>
<td>The intervention group had sit-stand desks installed at their workplace and received verbal instruction on their use, as well as written instructions on the correct ergonomic posture for both sitting and standing and the importance of regular postural change throughout the day. The control group had no change in desks and participants were advised to maintain usual day-to-day activity. The participants were probably aware of their allocation. The authors do not report who gave the instructions to the intervention and control groups</td>
</tr>
<tr>
<td>Blinding of outcome assessment (detection bias)</td>
<td>Unclear risk</td>
<td>Not reported</td>
</tr>
<tr>
<td>Incomplete outcome data (attrition bias)</td>
<td>Low risk</td>
<td>Virtually no attrition: only one participant was missing from the control group because of a malfunctioning accelerometer-inclinometer</td>
</tr>
<tr>
<td>Selective reporting (reporting bias)</td>
<td>Low risk</td>
<td>All outcomes mentioned in the method section were reported. Study protocol was not available</td>
</tr>
<tr>
<td>Baseline comparability/imbalance</td>
<td>High risk</td>
<td>Baseline data for age and gender were similar. It seems probable that there were baseline imbalances in awareness and physical activity levels between intervention and control groups as participants to the intervention group were selected from an academic institution focused on sedentary behaviour research whereas participants in the control group were never involved in physical activity research</td>
</tr>
</tbody>
</table>
Validity of outcome measure | Low risk | The accelerometer-inclinometer is a valid instrument for the measurement of sitting time

Brakenridge 2016

**Methods**

- Random allocation by clusters
- Single-blind
- Study duration: 12 months
- Dropout: more than 45% in both groups.
- **Location:** Australia
- **Recruitment:** Participants were invited to attend an information session, during which eligibility was confirmed and informed written consent was obtained

**Participants**

- **Population:** Employees from an international property and infrastructure group, located at two cities: Sydney and Brisbane
- **Organisational-support intervention (ORG) group:** 9 teams with 117 employees
- **ORG + tracker group:** 9 teams with 93 employees
- **Demographics:**
  - Mean age: ORG group: 40.0 (SD 8.0), ORG + tracker group: 37.6 (SD 7.8)
  - % of males: ORG group: 60%, ORG + tracker group: 47%
  - BMI: ORG group: 25.0 (SD 3.4) kg/m², ORG + tracker group: 24.1 (SD 3.4) kg/m²

**Interventions**

- **Duration:** 12 months
- **Organisational-support intervention (ORG group):** Information booklet, five fortnightly emails consisting of chosen activity-promoting tips, comments from participants or managers, images of participants taking part in the ‘Stand Up, Sit Less, Move More’ message and the organisation’s branding
- **ORG + tracker group:** Organisational support combined with activity tracker

**Outcomes**

- **Outcome name, measurement time/tool (units of measurement)**
  - Changes in sitting/standing/stepping time during work hours (minutes/10-hour workday) and overall hours (minutes/16-hour) measured at 3 months and 12 months.
  - Transitions in positions measured by activPAL3 accelerometer-inclinometer
  - Self-reported health- and work-related outcomes
    - Health-related outcomes: stress (single item, 1-10 scale; higher scores indicate more stress), physical and mental health quality of life (12 items, 0-100 scale; higher scores indicate better quality of life)
    - Work-related outcomes (scale 1-10): job performance, job control, work satisfaction

**Notes**

The authors declared that they have no competing interests.

### Carr 2015

**Methods**

- Random allocation
- Single-blind
- Study duration: 8 months
- Drop out: 10% (five participants were lost to follow-up and one discontinued the intervention)

**Location:** USA

**Recruitment:** participants were recruited via an electronic advertisement on the company’s well-being website. The advertisement included a link to an online eligibility survey. Research staff contacted interested and eligible employees via telephone to schedule a baseline testing session
**Participants**

- **Population:** healthy adults working in full-time sedentary jobs at a large private company were invited to participate via an electronic advertisement on the company’s well-being website. They were physically inactive, overweight/obese.
- **Intervention group:** 27 participants
- **Control group:** 27 participants

**Demographics:**
- Mean age: intervention: 45.2 (SD 10.9), control 45 (SD 10.7),
- 70% participants were females in both intervention and control groups
- BMI: intervention 34.5 (SD 6.8) kg/m², control 33 (SD 5.6)kg/m²

**Interventions**

- **Duration of intervention:** 16 weeks
- **Intervention:** ergonomic workstation intervention; three activity-promoting emails/week and access to a seated active workstation (elliptical machine, activeLife Trainer)
- **Control:** ergonomic intervention and emails only.

**Outcomes**

- **Outcome name, measurement time/tool (units of measurement)**
  - Occupational sedentary time and physical activity (% workday in light, moderate and vigorous intensity) measured by accelerometer-inclinometer
  - Cardiometabolic risk factors (weight, fat mass, lean mass, waist circumference, resting systolic and diastolic blood pressure and resting heart rate)
  - Musculoskeletal discomfort (self reported)
  - Work productivity measured by Health and Work Performance Questionnaire
  - Cognitive function measured as self reported time spent concentrating on work

**Notes**

- The second author, Dr Christoph Leonhard, owns propriety rights to the activeLife Trainer. No other financial disclosures were reported by the authors.

</tbody>
</table>
Incomplete outcome data (attrition bias)

All outcomes

Low risk

54 of the 60 participants completed all assessments. Five were lost to follow-up and one discontinued the intervention thus yielding a total attrition of 10%.

Selective reporting (reporting bias)

Low risk

All outcomes mentioned in the method section were reported.

Baseline comparability/imbalance

Low risk

Mean age: intervention: 45.2 (10.9), control 45 (10.7), 70% participants were females in both intervention and control groups, BMI: intervention 34.5 (6.8) kg/m², control 33 (5.6)kg/m².

Validity of outcome measure

Low risk

The accelerometer is a valid instrument for the measurement of sitting time.

---

**Chau 2014**

**Methods**

Random allocation with cross-over and wait-list control

Participants were allocated randomly by drawing from the ballot four at a time. The first four were allocated to intervention group and next four to control group for four weeks. The remaining participants were assigned to the wait-list control condition and were placed on the waiting list in seven groups (four to five people per group). After the initial four weeks, the previous control group received the intervention with the next group from the ballot draw serving as their controls. This was repeated until all nine groups had received the intervention.

Unblinded

- **Study duration:** 9 weeks
- **Dropout:** 7%
- **Location:** Australia
- **Recruitment:** project was advertised to staff as part of their workplace wellness program via internal mail, staff meetings and information fliers in the office. Staff members who were interested in participating contacted the research team and received additional project information and an expression of interest form. They could then join the study ballot by returning the expression of interest form.

**Participants**

- **Population:** staff from a non-government health agency in New South Wales, Australia

- **Demographics:**
  - BMI (kg/m²): underweight (< 18.5): 13%, normal range (18.5-24.9): 50%, overweight (25-29.9): 25%, obese (≥ 30): 13%

**Interventions**

- **Duration of intervention:** 9 weeks
- **Intervention:** sit-stand desk
- **Control:** no sit-stand desk
Outcomes

<table>
<thead>
<tr>
<th>Outcome name, measurement time/tool (units of measurement)</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Changes in self-reported and objectively assessed time spent sitting, standing and walking/stepping (minutes/day) before and after the use of a sit-stand desk measured by ActivPALs and self-report questionnaires.</td>
</tr>
<tr>
<td>• Domain specific sitting (minutes/day) over the whole day, assessed by self-report.</td>
</tr>
</tbody>
</table>

Notes

This research was supported by funding from Heart Foundation New South Wales, and Australian National Health and Medical Research Council Program Grant (#569940)

Risk of bias

<tr>
<td>Baseline comparability/ imbalance</td>
<td>Low risk</td>
<td>Since the trial used a cross-over design, all the participants would receive the interventions at some point</td>
</tr>
</tbody>
</table>
Validity of outcome measure  | Low risk  | The accelerometer is a valid instrument for the measurement of sitting time

**Chau 2016**

**Methods**
- Non-random allocation: CBA
- Single-blind
- Study duration: 20 weeks
- Dropout: 22%
- **Location:** Australia
- **Recruitment:** the research team gave a presentation about the study to team leaders and managers, who then discussed the study with their staff. Participants joined the study by returning a signed consent form to the researchers

**Participants**
- **Population:** customer care (call centre) staff from two teams working at one worksite of a large telecommunications company in Sydney, Australia
- **Intervention group:** 16 participants
- **Control group:** 15 participants
- **Demographics:** Mean age: control 35.1 (SD 11.5), intervention 31.0 (SD 10.0) The intervention group had higher BMI than control group.

**Interventions**
- **Duration:** 19 weeks
- **Intervention:** sit-stand desk + email reminders
- **Control:** no sit-stand desk

**Outcomes**
- **Outcome name, measurement time/tool (units of measurement)**
  - Changes in sitting/standing/walking time (minutes/8-hour workday) measured at 1 week, 4 weeks and 19 weeks. Transitions in positions measured by activPAL3 accelerometer-inclinometer and a self-administered questionnaire
  - Self-reported perceptions about work, work-related energy, and feelings at work at baseline, 4, and 19 weeks post-installation of sit-stand desks (intervention)

**Notes**
- A co-author, Amanda Sainsbury has received payment from Eli Lilly, the Pharmacy Guild of Australia, Novo Nordisk, and the Dietitians Association of Australia for seminar presentations at conferences. She is also the author of The Don't Go Hungry Diet (Bantam, Australia, and New Zealand, 2007) and Don't Go Hungry For Life (Bantam, Australia, and New Zealand, 2011)

</tr>
</tbody>
</table>
• GMI (group motivational interviewing) and environmental modifications (3 clusters; 92 employees); GMI derived from Motivational Interviewing (MI). MI is a counselling style that stimulates behavioural change by focusing on exploring and resolving ambivalence. A group setting has several benefits, e.g. sharing experiences, providing feedback and giving support.
• Environmental modifications (3 clusters; 96 employees): 1) the VIP Coffee Corner Zone - the coffee corner was modified by adding a bar with bar chairs, a large plant and a giant wall poster (a poster visualizing a relaxing environment, e.g. wood, water and mountains); 2) the VIP Open Office Zone - the office was modified by introducing exercise balls and curtains to divide desks in order to reduce background noise; 3) the VIP Meeting Zone - conference rooms were modified by placing a standing table (a table that allows you to stand while working) and a giant wall poster (as before); and 4) the VIP Hall Zone - table tennis tables were placed and lounge chairs were introduced in the hall for informal meetings. In addition, footsteps were placed on the floor in the entrance hall to promote stair walking.
• GMI (7 cluster; 118 employees);
• No intervention or control group (6 cluster; 106 employees)

### Danquah 2017

**Methods**
- Random allocation by clusters
- Single-blind
- Study duration: 3 months
- Dropout: Denmark
- **Location**: recruited through a press release and an open invitation in an electronic newsletter aimed at practitioners and health workers in municipalities and private workplaces all over Denmark

**Participants**
- **Population**: practitioners and health workers in municipalities and private workplaces all over Denmark
- **Intervention group**: 173 participants in 10 offices
- **Control group**: 144 participants in 9 offices
- **Demographics**:
  - Mean age: intervention 46 (SD 10), control 45 (SD 11)
  - % of females: intervention 61%, control 73%
  - BMI: intervention group 26 (SD 5.0) kg/m², control group 27 (SD 4.8) kg/m²

**Interventions**
- **Duration**: 3 months
- **Intervention**: a multi-component work-based intervention (ambassadors, environmental changes, lecture, workshop, emails and texts)
- **Control**: no intervention

**Outcomes**
- **Outcome name, measurement time/tool (units of measurement)**
  - Changes in sitting, standing and number of prolonged sitting periods (> 30 min) - minutes/8-hour workday, number of sit-to-stand transitions per hour in a workday, leisure sitting time and MVPA in leisure (minutes/8-hour leisure) measured at 1 and 3 months. Transitions in positions measured by activPAL3 accelerometer-inclinometer and a self-administered questionnaire
  - Weight (kg), waist circumference (cm), fat free mass (kg), fat mass (kg), body fat percentage at 3 months
**Risk of bias**

**De Cocker 2016**

### Methods
- **Random allocation by clusters**
- **Single-blind**
- **Study duration:** 3 months
- **Dropout:**
  - **Location:** Belgium
  - **Recruitment:** employees were invited to participate by email

### Participants
- **Population:** employees of 2 companies (a university and an environmental agency) in Flanders
- **Intervention group:** tailored group: 78 participants (2 departments), Generic group: 84 participants (2 departments)
- **Control group:** 51 participants (2 departments)
- **Demographics:**
  - Age in years: tailored 40.5 (SD 8.6), generic 40.7 (SD 9.7), control 39.3 (SD 9.0)
  - % of males: tailored 32%, generic 27%, control 15%
  - % of participants with high school/university education: tailored 58%, generic 70%, control 46%
  - **BMI:** tailored 24.2 (3.1) kg/m², generic 23.6 (SD 3.5) kg/m², control group 23.7 (SD 3.5) kg/m²

### Interventions
- **Duration:** 3 months
- **Intervention:** tailored group: personalised computer-tailored feedback about sitting time, including tips and suggestions on how to interrupt (taking short standing breaks) and reduce (replacing sitting by periods of standing) sitting, and in the end motivated participants were invited to create an action plan to convert intentions into specific actions
- **Generic group:** generic information on the importance of reducing and interrupting sitting
- **Control:** usual lifestyle

### Outcomes
- **Outcome name, measurement time/tool (units of measurement)**
  - Self-reported changes in sitting (total sitting, sitting at work, domains of leisure sitting) measured at 3 months

### Notes
- The first author is supported by the Research Foundation Flanders (FWO) (postdoctoral research fellowship: FWO11/PDO/097). Authors declared no conflict of interest

</tbody>
</table>

**Location:** USA

**Recruitment:** A word-of-mouth search was performed for finding interested companies to host the study and Caldrea Inc. volunteered. A recruitment presentation was made at an all-employee meeting (n ~ 50) and was followed a few days later by enrolment interviews.

### Participants

**Population:** employees of Caldrea Inc. company, USA

**Demographics:** average age: 40.4 years; out of 28 participants, 19 were female

### Interventions

**Duration of intervention:** 4 weeks

**Intervention:** sit-stand desk

Three different models of desks were used: Workfit-S, a setup that attaches to the front of one’s existing desk that can hold the computer monitor, keyboard and mouse; Workfit-A, a setup that is identical to Workfit-S but attaches to the back of one’s existing desk; and Workfit-D, a whole desk that is easily moved up and down. The Workfit-A and S also came with an added work-surface and all three types of desks came with anti-fatigue floor mats for comfort during standing.

**Control:** no sit-stand desk

### Outcomes

**Outcome name, measurement time/tool (units of measurement)**

Sitting time, standing time, and light activity at work self-reported and objectively assessed with accelerometer-inclinometer

Self-reported energy and relaxation levels

### Notes

James A. Levine has patents in accelerometer algorithms with Gruve Technologies Inc. but he did not access or analyse the raw the data from the Gruve device.

### Risk of bias

</tr>
</tbody>
</table>
Incomplete outcome data (attrition bias)
All outcomes

If we assume a person works for 40 hours per week, then for 28 participants the working hours will be 8960 hours for 8 weeks (4 weeks intervention and 4 weeks control period). However the study reported only 7,729 working hours based on accelerometer data.

Selective reporting (reporting bias)
Low risk

All outcomes mentioned in the methods section were reported. The study protocol was not available.

Baseline comparability/ imbalance
Low risk

There were no significant differences in age or BMI between interventions and control groups. Most of the participants were female.

Validity of outcome measure
Low risk

The accelerometer is a valid instrument for the measurement of sitting time.

Ellegast 2012

Methods
Random allocation
Unblinded
Study duration: 12 weeks
No dropouts

Location: Germany

Only part of the study was presented as all the data have not been analysed.

Participants
Population: desk-based employees at VDU workplaces
Demographics: mean age (years): 40.7 (range 24 to 58), control 42.1 (range 25 to 61)
4 female participants in both intervention and control groups
Mean BMI: 26.3 (SD 3.2) kg/m²

Interventions
Duration of intervention: 12 weeks

Intervention
● A recreational intervention consisting of sit-stand workplaces: 1) electrically adjustable (68cm to 118cm) writing desk and PC-table; 2) height and angle adjustable lecterns in that were also movable in the room combined with a foot stand; 3) stand tables during breaks; 4) table tennis in the cellar; 5) individual changes to the VDU station plus oral and written instructions to use printers further away and to use stairs.
● A behavioural intervention: 1) midday gymnastics (11.45am-12.00 am) with relaxation, stretch, power and co-ordination exercises; participants were instructed to participate every day; 2) action: cycle to work: every day participants could indicate if they cycled to work and be eligible for a prize; 3) afternoon (lunch?) walk; 4) company sports offer; 5) bonus point system: for every activity performed the participants got points that could be exchanged for small extras: apples, muesli bar etc.; 6) AiperMotion: participants wore an activity monitoring device that they could read anytime; 7) step
barometer; every week the results of the step counter in the AiperMotion device was published as an average over the week for every participant in one chart.

**Control:** usual office work

### Outcomes

**Outcome name, measurement time/tool (units of measurement)**
- Assessment of physical activity: changes in standing and sitting (min/day), number of steps and energy expenditure
- Assessment of well-being and medical check-up: body mass index, multidimensional mood questionnaire, general medical examination

### Notes

This project was initiated and funded by the German Social Accident Insurance (DGUV)

### Evans 2012

#### Methods
- **Random allocation:** RCT
- **Single-blind**
- **Study duration:** 10 days
- **Dropout:** 7%
- **Location:** United Kingdom
- **Recruitment:** healthy working adults who could stand unassisted recruited via poster and email

#### Participants
- **Population:** healthy adults working in an office at Glasgow Caledonian University in Scotland
- **Intervention group:** 14 participants (computer prompts (CP))
- **Control group:** 14 participants (education)
- **Demographics:** CP group (mean age 49 (SD 8 years) were older than the education group (mean age 39 (SD 10) years), predominantly female (11 in CP group and 11 in education group), worked as administrators (4 in CP group and 3 in education group), researchers (5 in CP group and 7 in education group), lecturers (5 in CP group and 4 in education group)
- **BMI:** CP group 23.7 (SD 3.5) vs. education group 23.6 (SD 2.8)

#### Interventions
- **Duration of intervention:** 5 days but the participants were followed up for 10 days.
- **Intervention:** CP + information
- **Control:** information only (a short educational talk)

#### Outcomes
- **Outcome name, measurement time/tool (units of measurement)**
  - Assessed with thigh-mounted accelerometer-inclinometer
  - Total sitting time (h/day)
  - Number of sitting events (events/day)
  - Number of prolonged sitting events (events/day)
  - Duration of prolonged sitting events (h/day)

#### Notes
- This study was funded by the School of Health, Glasgow Caledonian University and formed the dissertation project for Masters of Rehabilitation Science of Rhian Evans, Henrietta Fawole, and Stephanie Sheriff. No financial support was received from any commercial company. No financial disclosures were reported by the authors of this publication

</table>
Incomplete outcome data (attrition bias)  
All outcomes  
High risk  
The questionnaire was returned by 92 employees at baseline, before working at sit-stand desks, and 61 employees after 6 months. Those who completed the questionnaire only once were excluded, leaving 45 individuals who were included in the analysis. The study lost 49% participants during follow-up

Selective reporting (reporting bias)  
Low risk  
All outcomes mentioned in the protocol were reported.

Baseline comparability/imbalance  
High risk  
In the intervention group participants were older and had more experience of office work. 70.8% were females in the intervention group and 81% were females in the control group. BMI (kg/m²): intervention: 24.8 (3.9), control: 23.3 (3.8)

Validity of outcome measure  
High risk  
Validity of the questionnaire used in the study has not been tested

Gilson 2009

Methods  
Random allocation  
Unblinded  
Study duration: 10 weeks  
Dropout: 16%  
Location: UK, Australia and Spain  
Recruitment: participants came from 3 major regional universities in 3 countries, represented by a lead investigator in each university, who had expressed an interest in running an employee intervention at their respective university as part of an evolving, international project

Participants  
Population: white-collar (i.e. professional, managerial, or administrative) university staff from the UK (n = 64), Australia (n = 70) and Spain (n = 80)  
Intervention groups:  
- route walking group 60 participants;  
- incidental walking group 59 participants.  
Control group: 60 participants  
Demographics: mean age (years): route walking group 42.1 (SD 9.2); incidental walking group 41 (SD 9.7), control group 40.8 (SD 11.4)  
Women were predominant in all 3 groups  
Mean BMI (kg/m²): route walking group 25.1 (SD 4), incidental walking group 25.4 (SD 4.3), control group 24.2 (SD 3.8)
Interventions

Duration of intervention: 10 weeks
Interventions: walking strategies (route and incidental walking)
Control: no intervention

Outcomes

Outcome name, measurement time/tool (units of measurement)
- Number of steps assessed by an unsealed pedometer (Yamax SW-200) accompanied by a diary
- Sitting time (minutes/day) assessed by a logbook

Notes

Authors declared that they had no competing interests.

**Gordon 2013**

### Methods
- **Random allocation**
- **Unblinded**
- **Study duration:** 10 weeks
- **Dropout:** 14%
- **Location:** USA
- **Recruitment:** strategically placed fliers posted around the Arizona State University Downtown Phoenix Campus, email advertisements delivered to employees through the Employee Wellness Committee, and word of mouth

### Participants
- **Population:** currently employed adults with predominantly sedentary occupations working in the Greater Phoenix area in 2012-2013
- **Intervention group:** 12 participants
- **Control group:** 10 participants
- **Demographics:**
  - **Mean age:** intervention 44.2 (SD 12.5), control 47.2 (SD 13.5)
  - 50% females in both groups
  - **BMI:** intervention 24.1 (SD 3) kg/m², control 30.6 (SD 5) kg/m²
  - Intervention group composed of significantly more “official and managerial level” individuals

### Interventions
- **Duration of intervention:** 10 weeks
- **Intervention:** one orientation to walking workstation, 5 bi-weekly newsletters, specifically targeting workplace sitting behaviours, 5 bi-weekly FAQ’s and access to study website for intervention content, latest sedentary behaviour research and links for tools for decreasing sitting time at work
- **Control:** health education

### Outcomes
- **Outcome name, measurement time/tool (units of measurement)**
  - Sitting time/workday (minutes/8-hour workday) measured by accelerometer-inclinometer. Participants were also asked to complete a daily log to determine work schedule and verify obtained inclinometer and accelerometer data

### Notes
- Thesis presented in partial fulfilment of the requirements for the degree Master of Science

Workplace interventions for reducing sitting at work (Review)
Random sequence generation (selection bias) | Low risk | Group allocation was decided by tossing a coin.
Allocation concealment (selection bias) | Unclear risk | Not reported
Blinding of participants and personnel (performance bias) | Unclear risk | Not reported
Blinding of outcome assessment (detection bias) | Unclear risk | Not reported
Incomplete outcome data (attrition bias) | Low risk | One participant from both groups withdrew due to busy schedule; 1 participant from both groups was excluded due to device malfunction; and 1 participant from the control group was excluded due to refusal to wear accelerometer. Intention-to-treat analysis was followed for data analysis
Selective reporting (reporting bias) | Low risk | All outcomes mentioned in the method section were reported. Study protocol was not available
Baseline comparability/imbalance | High risk | Intervention group composed of significantly more "official and managerial level" individuals. Age of participants in the control group was 47.2 (SD 13.5) and in the intervention group was 44.2 (SD 12.5). There were 50% females in both groups. There was significant difference in BMI of participants between intervention and control groups
Validity of outcome measure | Low risk | The accelerometer is a valid instrument for the measurement of sitting time
Graves 2015

| Methods | Random allocation  
| Location: UK  
| Study duration: 8 weeks  
| Dropout: 4%  

**Recruitment:** consent was sought from 11 departmental managers for employee recruitment. All employees in consenting departments received an overview of the study and participant information sheet, and were invited to a study information session via an email from the research team.

| Participants | Population: office workers from one organisation (Liverpool John Moores University, Liverpool, UK). Employees within the approached departments were predominantly administrative staff  
| Intervention group: 26 participants  
| Control group: 21 participants  
| **Demographics:**  
| Mean age: intervention 38.8 (SD 9.8) years, control 38.4 (SD 9.3) years  
| 89% in intervention group and 67% in control group were females  
| BMI (kg/m²): intervention 67.4 (SD 13.8), control 70.5 (SD 16.4)  

| Interventions | **Duration of intervention:** 8 weeks  
| Intervention: sit-stand desk combined with face-to-face training and ergonomic information  
| Control: no intervention  

| Outcomes | **Outcome name, measurement time/tool (units of measurement)**  
| Sitting time, standing and walking time (minutes/day) measured by paper-based diary to record  
| Vascular outcomes: B-mode images of the brachial artery  
| Plasma glucose, triglycerides and total cholesterol  
| Musculoskeletal outcomes on a Likert scale from 0 (no discomfort) to 10 (extremely uncomfortable)  
| Acceptability and feasibility  

| Notes | Ergotron Ltd provided the sit-stand desks but had no involvement on the provenance, commissioning, conduct or findings of the study. No other financial disclosures were reported by the authors of this paper  

| Risk of bias | **Bias**  
| **Authors' judgement**  
| **Support for judgement**  
| Random sequence generation (selection bias) | Low risk  
| Participants were randomised using a randomised block design and random number table  
| Allocation concealment (selection bias) | High risk  
| One member of the research team assigned the participants to a treatment arm, based on a design and table with alternating scheme

Healy 2013

| Methods                                      | Non-random allocation by clusters (floor): CBA Unblinded Study duration: 3 months Dropout: 14% Location: Melbourne, Australia Recruitment: an invitation email was sent to all potential participants to attend one of two 30-minute study information sessions delivered by research staff. Participants who subsequently expressed interest were screened via telephone for eligibility |
| Participants                                 | Population: from a single workplace (Comcare: the government agency responsible for workplace safety, rehabilitation and compensation for Australian government workplaces) in metropolitan Melbourne, Australia Intervention group: 19 participants Control group: 19 participants Demographics: mean age 42.4 (SD 10.6) years in the intervention group and 42.9 (SD 10.3) years in the control group Women were predominant in the intervention group and men were predominant in the control group |
### Interventions

**Duration of intervention:** 4 weeks  
**Intervention:** the intervention communicated 3 key messages: “Stand Up, Sit Less, Move More” and had the following components:
- organisational (a 45-minute researcher-led consultation with unit representatives from the intervention group and management followed by a workshop for all intervention participants);
- environmental (installation of sit-stand desks); and
- individual elements (30-minute face-to-face consultation with each intervention participant, followed by 3 telephone calls (1/week)).
**Control:** no intervention

### Outcomes

**Outcome name, measurement time/tool (units of measurement)**
- Sitting, standing, and moving at the workplace (minutes/8-h workday) assessed by accelerometer-inclinometer at baseline and their changes at 3-month follow-up
- Weight (kg), waist circumference (cm), hip circumference (cm), fat free mass (kg), fat mass (kg), fasting blood lipids (mmol/L) and glucose (mmol/L) baseline vs. 3 months
- Self-reported health- and work-related outcomes baseline vs. 3 months
  - Musculoskeletal symptoms by anatomical regions
  - Other health symptoms: eye strain, headaches, digestion problems, trouble walking, trouble sleeping, fatigue (1-5 scale)
  - Work-related outcomes ≥ 1 sick day (in the last month), > 1 day worked while suffering health problems (in the last month), work performance (1-10 scale)

### Notes

This study was funded by an NHMRC project grant and the Victorian Health Promotion Foundation. Ergotron provided the height-adjustable desks (www.ergotron.com). No financial disclosures were reported by the authors and the authors declared that there were no conflicts of interest

### Risk of bias

<tr>
<td>BMI: intervention group 28.61 (SD 6.46) kg/m², control group 28.61 (SD 5.48) kg/m²</td>
</tr>
</tbody>
</table>
### Interventions

**Duration:** 3 months  
**Intervention:** multicomponent intervention composed of organisational (Consultation workshop, tailored email messages to promote organisational strategies by team champions) environmental (dual screen sit-stand desk), and individual-level strategies and targeted change at both the individual and the cluster levels (face to face coaching and telephone calls by study-trained health coaches)  
**Control:** usual practice

### Outcomes

**Outcome name, measurement time/tool (units of measurement)**  
- Changes in sitting/standing/stepping time (minutes/8-hour workday) and overall sitting time (minutes/16-hour) measured at 3 months and 12 months. Transitions in positions measured by activPAL3 accelerometer-inclinometer  
- Adverse events

| Validity of outcome measure | Low risk | activPal accelerometer is a valid instrument for assessing physical activity and sedentary behaviour |

Kress 2014

| Methods | Non-random allocation  
Study duration: 6 months  
Drop outs: 47%  
Location: United States  
Recruitment: participants were contacted by email with an invitation to participate in the study |

| Participants | Population: call centre workers in a company (healthways) in USA. Healthways Inc. , a well-being improvement company with headquarters in Franklin, Tennessee, has multiple call centres in which their Health Coaches, Clinicians (Nurses and Dieticians) , and Customer Service Representatives work  
Intervention: sit-stand desks (45 participants), standing desks(46 participants)  
Control: seated (47 participants)  
Demographics: mean age in years: sit-stand 34.8 (SD 11.5), standing 28.9 (6.8), seated 35 (SD 13.2)  
% female participants: sit-stand 71%, standing 59%, seated 70%  
BMI: sit-stand 29 (SD 9.13), standing 26.8 (SD 5.5), seated 27.8 (SD 5.7) |

| Interventions | Duration of intervention: 6 months  
Sit-stand desk vs. standing desk |

| Outcomes | Outcome name, measurement time/tool (units of measurement)  
- Self reported changes in sitting/standing (minutes/ workday) measured at 6 months  
- Energy expenditure (calories/minute)  
- Participants experiences with the new workstation at 6 months |

| Notes | Data for seated group not reported. |

MacEwen 2017

Methods
Random allocation
Single-blind
Study duration: 3 months
Dropout: 11%
Location: Australia
Recruitment: through posters and word-of-mouth

Participants
Population: full-time desk-based employees in the Charlottetown area.
Intervention group: 16 participants
Control group: 12 participants
Demographics:
Mean age in years: intervention 43.2 (SD 9.7), control 48.9 (SD 11.4)
BMI: intervention group 36.5 (SD 9) kg/m², control group 34.6 (SD 7) kg/m²

Interventions
Duration: 3 months
Intervention: sit-stand desk
Control: no sit-stand desk

Outcomes
Outcome name, measurement time/tool (units of measurement)
• Changes in sitting/standing/stepping time (minutes/8-hour workday) measured at 12 weeks. Transitions in positions measured by activPAL3 accelerometer-inclinometer
• Weight (kg), waist circumference (cm), BMI, body fat %, estimated VO2 max (ml/min/kg), systolic and diastolic BP (mmHg), fasting blood lipids (Total cholesterol/HDL/LDL/Triglycerides) (mmol/L), glucose (mmol/L), HbA1c (%), aortic augmentation Index (%), subendocardial variability (%) at 12 weeks

<td></td>
</tr>
<tr>
<td>• multi component: 12 participants;</td>
<td></td>
</tr>
<tr>
<td>• workstation only: 13 participants.</td>
<td></td>
</tr>
</tbody>
</table>
### Control group: 13 participants

**Demographics:** mean age in the multi component group was 37.3 (SD 10.7) years, 43 (SD 10.2) years in the workstation only group, and 48 (SD 11.6) years in the control group. There were no men in the multi component group, 3 in the workstation only group, and 4 in the control group.

### Interventions

**Duration of intervention:** 3 months

**Interventions:**
- multi-component intervention consisted of the installation of height-adjustable workstations and organisational-level (management consultation, staff education, manager emails to staff) and individual-level (face-to-face coaching, telephone support) elements;
- workstation-only intervention consisted of the installation of height-adjustable workstations and occupational health and safety instructions from the project manager.

**Control:** no intervention

### Outcomes

**Outcome name, measurement time/tool (units of measurement)**

All outcomes were assessed at 3-month follow-up:
- Changes in sitting, standing, and moving at work (minutes/8-h workday) assessed with an accelerometer-inclinometer
- Musculoskeletal symptoms by anatomical regions
- Work related outcomes: work performance, ≥ 1 sick day (in the last month), > 1 day worked while suffering health problems (in the last month)
- Study feasibility and acceptability
- Adverse events

### Notes

Funding source: Australian Postgraduate Award Scholarship, UQ School of Population Health Top-Up Scholarship and research student funding, Queensland Health Core Infrastructure Funding, and UQ Major Equipment and Infrastructure and NHMRC Equipment Grant.

Height-adjustable workstations were provided by Ergotron.

No other financial disclosures were reported by the authors.

### Pedersen 2013  
(Continued)

| Validity of outcome measure | Low risk | Occupational Sedentary and Physical Activity Questionnaire (OSPAQ) which had moderate validity was used for assessing time spent sitting at work |

### Pickens 2016

#### Methods
- Non-random allocation: CBA
- Study duration: 6 months
- Dropout: 45%
- **Location:** United States
- **Recruitment:** email from human resource department of company

#### Participants
- **Population:** employees of a call centre company in the Eastern United States
- **Intervention group:** sit-to-stand (45 participants) and standing (46 participants)
- **Control group:** seated (47 participants)
- **Demographics:**
  - Mean age in years: sit-stand group: 34.8 (SD 11.5), stand group: 28.9 (SD 6.8), seated group: 35.0 (SD 13.2)
  - % of females: sit-stand group 71.1%, stand group 58.7%, seated group 70.2%
  - BMI: sit-stand group 29.0 (SD 9.1) kg/m², stand group 26.8 (SD 5.5) kg/m², seated group 27.8 (SD 5.7) kg/m²

#### Interventions
- **Duration:** 3 months
- Sit-to-stand vs. standing vs. seated workstation

#### Outcomes
- **Outcome name, measurement time (units of measurement)**
  - Proportion of monitored time in each activity level - sedentary, light, moderate and vigorous activity at 3 months and 6 months
  - Steps per minute at 3 months and 6 months

#### Notes
- Authors have not reported post intervention values for seated control group

### Risk of bias

<tr>
<th>Random allocation by cluster</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single blind</td>
</tr>
<tr>
<td>Study duration: 27 weeks</td>
</tr>
<tr>
<td>Location: Spain</td>
</tr>
<tr>
<td>Recruitment: office workers were first invited to participate in an on-line survey to identify those with low and moderate PA levels. Then they were invited to participate in the intervention by email or phone calls</td>
</tr>
</tbody>
</table>

### Participants

| Population: administrative and academic staff working at six campuses in four Spanish Universities in Galicia, the Basque Country and Catalonia |
| Intervention group: 135 participants (3 clusters) |
| Control group: 129 participants (3 clusters) |

### Interventions

| Duration of intervention: 8 weeks |
| Intervention: automated web-based intervention (W@WS) to encourage incidental walking and short walks during the workday. The walking strategies focused on breaking occupational sitting time by incidental walking into work tasks such as moving rather than sitting during lectures and seminars, not sitting to take phone calls, short walks (5-10 minutes) within University campuses, active transport (e.g., walking to work whenever possible) or active lunch breaks |
| Control: no intervention |

### Outcomes

<table>

**Sandy 2016**

Methods

- Random allocation
- Single-blind
- Study duration: 14 weeks
- Dropouts: 14%

**Location:** Australia

**Recruitment:** participants were recruited via an email
### Participants

**Population:** employees of Lockheed Martin Mission System and Training business unit: primarily develops software solutions and training/simulation technologies for both civil and commercial markets. 2500 full-time employees of whom 90% in sedentary computer work for a large percentage of their workday

**Intervention group:** ergonomic training (16 participants), adjustable desks (23 participants), training and desks (20 participants)

**Control group:** 13 participants

**Demographics:**
- Mean age in years: 37.2 (SD 9.4)
- BMI: 26.9 (SD 4.4) kg/m²

### Interventions

**Duration of intervention:** 14 weeks

**Intervention:** Training vs. adjustable desks vs. training and desks

**Control:** no intervention

### Outcomes

**Outcome name, measurement time/tool (units of measurement)**
- Changes in sitting/standing/walking time (minutes/9-hour workday) assessed by self report at week 1, 2, 3, 4, 6, 10, 14
- Discomfort level, musculoskeletal pain, fatigue

### Risk of bias

**Bias** | **Authors’ judgement** | **Support for judgement**
---|---|---
Random sequence generation (selection bias) | Low risk | Participants were listed out in Excel and randomly placed into one of the four groups
Allocation concealment (selection bias) | Unclear risk | Not reported
Blinding of participants and personnel (performance bias) | Unclear risk | Not reported
Blinding of outcome assessment (detection bias) | Unclear risk | Not reported
Incomplete outcome data (attrition bias) | Low risk | < 10% attrition rate
Selective reporting (reporting bias) | Low risk | No protocol; all the outcomes mentioned in the methods section are reported
Baseline comparability/ imbalance | Unclear risk | Baseline characteristics of participants not reported
### Validity of outcome measure

| High risk | Only mentioned self report. No information on validity of questionnaires used |

### Schuna 2014

#### Methods

**Random allocation**

**Single-blind**

**Study duration:** 3 months

**Dropouts:** 24%

**Location:** USA

**Recruitment:** in-house distribution of print and electronic media. Potential participants received an email providing a link to an online survey that included a series of screening questions designed to assess participant eligibility.

#### Participants

**Population:** pool of 728 overweight/obese and sedentary employees at a single office

**Intervention group:** 15 participants

**Control group:** 16 participants

**Demographics:** mean age: intervention 40 (SD 9.5) years, control 40.3 (SD 10.9) years

One male participant and 40 female participants

**BMI:** intervention 36.1 (SD 8.7) kg/m², control 35.6 (SD 8.2) kg/m²

#### Interventions

**Duration of intervention:** 3 months

**Intervention:** treadmill desk plus counselling

**Control:** no intervention

#### Outcomes

**Outcome name, measurement time/tool (units of measurement)**

Physical activity (minutes/hour) and sedentary behaviour (minutes/hour) measured by accelerometer-inclinometer

Body mass, body fat percentage, and BMI

#### Notes

This research was supported by Blue Cross and Blue Shield of Louisiana

### van Berkel 2014

#### Methods
- Random allocation
- Unblinded
- Study duration: 12 months
- Dropout: 11%
- **Location**: Amsterdam, the Netherlands

#### Participants
- **Population**: all employees from 2 Dutch research institutes were invited to participate, between April and November 2010
- **Intervention group**: 129 participants
- **Control group**: 128 participants
- **Demographics**: mean age of the study population was 46 years
- 67% of participants were women
- About 60% of the study population had a healthy weight (BMI 18.5-25)

#### Interventions
- **Duration of intervention**: 6 months but the participants were followed up for 12 months
- **Intervention**: the Mindful VIP intervention consists of 8 weeks of in-company mindfulness training with homework exercises, followed by 8 sessions of e-coaching. The homework exercises comprised a variety of formal (“body scan” meditation, sitting meditation) and informal exercises (small exercises, such as breathing exercises when starting up the computer, and grocery shopping mindfully). Additionally, free fruit and snack
vegetables were provided during the 6 months. In addition, lunch walking routes, and a buddy-system were offered as supportive tools

**Control:** received information on existing lifestyle behaviour-related facilities that were already available at the worksite

**Outcomes**

van Berkel 2014  
(Continued)

| Validity of outcome measure | High risk | Validity of the questionnaire used in the study has not been tested |

Verweij 2012

| Methods | Allocation randomly by cluster  
Double-blind  
Study duration: 6 months  
Dropout: 43% in occupational physicians (OPs) and 10% in employees  
Location: Amsterdam, the Netherlands  
Recruitment: OPs were recruited by the Netherlands Society of Occupational Medicine via a direct mailing to their members' registry (≥ 2100 OPs). OPs were asked to recruit 1 or more companies of medium or large size (≥ 100 workers). Next, OPs recruited employees via a health risk appraisal consisting of anthropometric measurements and subsequent health advice |

| Participants | Population: OPs from the Netherlands Society of Occupational Medicine and employees from medium or large sized companies in the Netherlands  
Intervention group: OPs (n = 7), employees (n = 274)  
Control group: OPs (n = 9), employees (n = 249)  
Demographics: mean age of employees in the intervention group was 46 (SD 8) years, mean age in the control group was 48 (SD 9) years. Percentages of men were 62% and 65% in the intervention and control groups respectively. 33% of employees in the intervention group and 27% of employees in the control group had a normal BMI  
Type of worker  
Intervention group: blue collar (manual labour) 15%; white collar 70%; client contact 15%  
Control group: blue collar 17%; white collar 73%; client contact 10% |

| Interventions | Duration of intervention: 6 months  
Intervention: guideline-based counselling by OP providing advice to employers on how to assess and intervene on the obesogenic work environment. Conducted by OPs as 5 face-to-face behavioural change counselling sessions for employees to improve their lifestyle to prevent weight gain  
Control: usual care by physician |

| Outcomes | Outcome name, measurement time/tool (units of measurement)  
- Sitting at work and leisure (minutes/day) assessed by a questionnaire  
- Physical activity assessed by Short questionnaire to assess health enhancing physical activity (SQUASH)  
- Dietary behaviour (daily servings/week): fruit intake assessed by Short Fruit and Vegetable questionnaire, consumption of energy-dense snacks was assessed by using the fat list  
- Weight-related measures: waist circumference (cm), body weight (kg) and body height (cm) |
Notes

This study was funded by the Netherlands Organisation for Health Research and Development. The authors report no conflicts of interest

### Interventions

The organisational plus technology support intervention lasts for 8 weeks and consists of the following components:

- a participant information session (30-45 minutes);
- an electronic information booklet;
- a unit representatives’ consultation workshop (2-4 hours);
- the training of team managers;
- PLUS technology support: participants will wear a LUMOback posture sensor device around their waists for 8 weeks.

**Control:** will receive all the elements of the intervention except PLUS technology support.

### Outcomes

**Primary outcome**

- Daily sitting time and workplace sitting time assessed objectively using an activPAL accelerometer-inclinometers

**Secondary outcomes**

- Mediators and moderators of any change
- Reliability and validity of the LUMOback
- Standing and moving time (a) at the workplace and (b) across the day

### Starting date

It is unclear whether the study has started despite mentioning anticipated date of first participant enrolment 17/03/2014. The study registration has not been updated.

<table>
<thead>
<tr>
<th>Trial name or title</th>
<th>The Inphact treadmill study</th>
</tr>
</thead>
</table>

**Methods**

Random allocation

**Location:** Sweden

**Recruitment:** recruitment and screening of participants has been completed

### Participants

**Population description:** healthy overweight and obese office workers (n = 80) with mainly sedentary tasks will be recruited from office workplaces in Umeå, Sweden

### Interventions

The intervention group will receive a health consultation and a treadmill desk, which they will use for at least one hour per day for 13 months

**Control:** the control group will receive the same health consultation, but continue to work at their regular workstations

### Outcomes

**Primary outcome:**

Physical activity and sedentary time during workdays and non-workdays as well as during working and non-working hours on workdays will be measured objectively using accelerometers (Actigraph and activPAL) at baseline and after 2, 6, 10, and 13 months of follow-up

**Secondary outcome:**

Food intake will be recorded and metabolic and anthropometric variables, body composition, stress, pain,

### Dunstan 2014

**Interventions**
The intervention consists of four distinct components:
- an initial unit representatives’ consultation;
- a whole-of-workplace Information session;
- environmental modification involving installation of sit-stand workstations for individual participants;
- support for behavioural change which includes:
  - an initial one-on-one individual consultation with project staff;
  - 4 telephone support calls over 3 months;
- support for behavioural change which includes:
  - an initial one-on-one individual consultation with project staff;
  - 4 telephone support calls over 3 months.

**Control:** no intervention

**Outcomes**

**Primary outcome**
- A 30 minutes/day reduction in objectively-assessed (using physical activity monitors) workplace sedentary time
- An increase of 5 breaks/day in workplace sedentary time, objectively measured using physical activity monitors

**Secondary outcomes**
Examine the effect of the intervention on cardiometabolic markers of health and disease including:
- body composition including waist circumference, BMI, and percent fat mass;
- fasting blood levels of glucose, insulin and lipids;
- blood pressure.

Explore workplace and individual-level mediators (how did the intervention work?) and moderators (for whom did it work?) of change using a specially formulated questionnaire

### Finkelstein 2015

**Trial name or title**
TRial of Economic Incentives to Promote Physical Activity (TRIPPA)

**Methods**
Random allocation

**Location:** Singapore

**Recruitment:** on a rolling basis, and in two steps. In the first step, companies were engaged through existing contacts and “cold calls”. If companies responded positively, a study briefing was conducted to apprise the management of study details. Once we received confirmation of participation from the management team, we proceeded to step two of the recruitment process. Recruitment materials (e.g., electronic direct mails, posters, and newsletters) communicating the nature of the research study were disseminated to employees through internal channels unique to each company. The materials directed potential participants to the study website for additional information. Employees were also invited to attend a presentation conducted by the study team at each participating worksite

**Participants**
**Population description:** employees from 13 companies spanning 15 worksites in Singapore

### Mantzari 2016

**Trial name or title**

Methods

- **Random allocation**
- **Location**: United Kingdom
- **Recruitment**: will be recruited through: 1) employment databases and invited via letter/email, and 2) adverts in local newsletters and flyers posted within the buildings of target organisations

**Participants**

- **Population description**: office-based employees from two companies in Cambridge, UK

**Interventions**

- **Intervention**: sit-stand desks
- **Control**: no intervention

**Outcomes**

- Physical activity energy expenditure estimated via Actiheart monitors
- Sedentary behaviour measured using activPAL inclinometers: sitting time during a) working hours (workplace sitting time) and b) all waking hours (total sitting time); sitting patterns (number of sit-to-stand transitions; sitting time accrued in prolonged bouts (≥ 30 min)) during a) working hours (workplace sitting patterns) and b) all waking hours (total sitting patterns)
- Cardio-metabolic related outcomes: BMI calculated from weight and height; weight measured using a scale; height measured using a stadiometer; fat mass and fat-free mass measured via a spectroscopy device; blood pressure, measured via an electronic monitor; waist-hip circumference measured using a tape measure; plasma total cholesterol, HDL, triglycerides and HbA1C, measured via non-fasting blood tests
- Musculoskeletal discomfort measured using the Nordic Musculoskeletal Questionnaire [80]
- Ability to work, work productivity, presenteeism, absenteeism and job satisfaction measured using the Work ability index

**Starting date**

**Contact information**

- Correspondence: tm388@medschl.cam.ac.uk

**Notes**

The study is supported by a grant from the Department of Health Policy Research Program (Policy Research Unit in Behaviour and Health [PR-UN-0409-10109]), the Medical Research Council (Unit Programme number MC_UU_12015/3) and the British Heart Foundation (Intermediate Basic Science Research Fellowship grant FS/12/58/29709 to KW)

### Martin-Borras 2014

**Trial name or title**

SedestActiv Project

**Methods**

- **Random allocation**
- **Location**: Spain
- **Recruitment**: a total of 232 subjects will be randomly allocated to an intervention and control group (116 individuals each group). In addition, 50 subjects with fibromyalgia will be included

**Participants**

- **Population description**: professionals from 13 primary health care centres will randomly invite mildly obese or overweight patients of both genders, aged 25-65 years, to participate

**Interventions**

- **6-month primary care intervention**
- **Control**: no intervention
### Outcomes

**Duration of intervention:** 6 months  
**Primary outcome:** to assess the effectiveness of a 6-month primary care intervention to reduce diary hours of sitting time in overweight and obese patients, as well as to increase their weekly energy expenditure

**Secondary outcomes**
- Number of steps walked
- Subjective level of physical activity
- Quality of life related to health
- Blood pressure
- Skin folds and waist circumference
- Triglycerides, total cholesterol and glucose

#### Starting date
June 2012

### NCT01787643

**Trial name or title**

**Methods**  
Random allocation  
**Recruitment:** active, not recruiting

**Participants**  
**Population:** sedentary office employees

**Interventions**  
Height-adjustable desk installation in office

**Outcomes**  
**Primary outcome:** workplace sitting time  
**Secondary outcomes**
- Total sitting time
- Energy expenditure
- Body weight, BMI, fat mass reduction
- Changes in musculoskeletal symptoms
- Increase in standing behaviour

#### Starting date
January 2013

#### Contact information

#### Notes
**Study sponsor:** USDA (United States Department of Agriculture) Grand Forks Human Nutrition Research Center
### NCT01846013

**Trial name or title**  
Methods
Random allocation  
**Recruitment:** active, not recruiting

**Participants**  
**Population:** sedentary employees who use a single computer workstation for the majority of their workday

**Interventions**  
Sit-stand workstation with three arms  
- **Stand:** standing for at least half of the workday at work (4 hours)  
- **Move:** increase movement time at work. Move more by making small changes (walking meetings, take stairs, etc.)  
- **Stand and Move:** increase standing time to half of workday (4h) and increase movement time at work.

**Outcomes**  
- Total physical activity  
- Fasting blood glucose  
- Total cholesterol  
- Body composition

**Starting date**  
November 2013

**Contact information**

**Notes**  
**Study sponsor:** University of Minnesota - Clinical and Translational Science Institute

### NCT02376504

**Trial name or title**  
Modifying the workplace to decrease sedentary behaviour and improve health

**Methods**  
Random allocation

**Participants**  
Healthy volunteers employed in a full-time sedentary job

**Interventions**  
**Duration of intervention:** 12 months  
Three-arm trial  
**Intervention:** treadmill workstation and sit-stand workstation  
**Control:** participants will be asked to engage in three 10 min walking bouts each workday

**Outcomes**  
Change in weight

**Starting date**  
April 2014

**Contact information**  
Anne Thorndike, email: ATHORNDIKE@mgh.harvard.edu

**Notes**  
**Study sponsor:** Northeastern University

### NCT03236597

**Trial name or title**

Random allocation

**Participants**

Desk-based employees

**Interventions**

Treadmill workstation versus sit-stand workstation

**Outcomes**

- Time spent sitting, standing, and moving measured by the ActivPAL at 7 days follow-up
- Cardiometabolic risk profile measured via a composite score of fasting glucose, insulin, triglycerides, HDL-cholesterol and blood pressure

**Starting date**

August 2017

**Contact information**

Mark Pereira, perei004@umn.edu

**Notes**

O’Connell 2015

### O’Connell 2015

**Trial name or title**

SMArT Work: Stand More AT Work

**Methods**

Random allocation in clusters

**Location:** UK

**Recruitment:** participant recruitment will be coordinated via the research team at the Leicester Diabetes Centre. The study team currently hold a database of office units within the University Hospitals of Leicester NHS Trust and will promote this study to them initially through the use of the Trust’s intranet and emails to department managers. This will be followed up with a face-to-face presentation/meeting if necessary

**Participants**

Desk-based office workers (n = 238) from a stratified sample of NHS staff (e.g. employees, managers, gender, job role)

**Interventions**

Height-adjustable workstations at the environmental, organisational and individual level that support less occupational sitting

**Outcomes**

- Primary outcome is a reduction in sitting time, measured by the activPALTM micro at 12 months.
- Secondary outcomes include objectively measured physical activity and a variety of work-related health and psycho-social measures.

**Starting date**

October 2014

**Contact information**

Dr Ben Jackson, email: b.r.jackson@lboro.ac.uk

**Notes**

126 Workplace interventions for reducing sitting at work (Review)

CONTRIBUTIONS OF AUTHORS
Jos Verbeek, Sharea Ijaz, and Nipun Shrestha conceptualised the review.
Nipun Shrestha took the lead in writing the protocol.
Kaisa Neuvonen (Information Specialist, Cochrane Work Group) and Nipun Shrestha designed the systematic search strategies.
Nipun Shrestha and Katriina Kukkonen-Harjula conducted the study selection.
Nipun Shrestha, Suresh Kumar, Chukwudi Nwankwo, Veerle Hermans, and Soumyadeep Bhaumik did the data extraction and 'Risk of bias' assessment for the previous versions.
Nipun Shrestha, Veerle Hermans, and Sharea Ijaz did the data extraction and 'Risk of bias' assessment for the current update.
Nipun Shrestha, Jos Verbeek, and Zeljko Pedisic conducted the data analysis.
Nipun Shrestha wrote the manuscript collaborating with Jos Verbeek, Katriina Kukkonen-Harjula, Sharea Ijaz, Veerle Hermans, and Zeljko Pedisic.

DECLARATIONS OF INTEREST
Nipun Shrestha: None known.
Jos Verbeek: I am employed by the Finnish Institute of Occupational Health to co-ordinate the Cochrane Work Group.
Sharea Ijaz: None known.
Katriina T Kukkonen-Harjula: None known.
Veerle Hermans: None known.
Zeljko Pedisic: None known.

SOURCES OF SUPPORT

Internal sources
- Cochrane Work Review Group, Finland.
Nipun Shrestha attended a three-month internship to learn about Cochrane systematic review methodology.

External sources
- NIHR CLAHRC West, UK.
S Ijaz's time for this update was supported by National Institute for Health Research (NIHR) Collaboration for Leadership in Applied Health Research and Care West (CLAHRC West) at University Hospitals Bristol NHS Foundation Trust.
- Victoria University, Australia.
Nipun Shrestha has received financial support through a VU Research Scholarship 2016 from Victoria University.
DIFFERENCES BETWEEN PROTOCOL AND REVIEW

We added time spent in prolonged sitting bouts (e.g., 30 minutes or more) and number of such bouts, total time spent sitting, including sitting at and outside work, time spent standing and stepping at work as new outcomes in the review. We added the number and duration of prolonged sitting bouts as outcomes because research has suggested that breaking up sitting time may be beneficial to health (Dunstan 2011). We added the total time spent sitting, including sitting at and outside work, as an outcome because reducing occupational sitting time may lead to an increase of time spent sitting in non-occupational domains. The possibility of such compensatory effects has been described in previous papers (Gomersall 2013; Pedišić 2017). We added the amounts of time spent standing and stepping at work as outcomes because the amount of time in a 24-hour day is fixed and every reduction of time spent sitting has to necessarily result in a proportional increase of time spent in one or more other time-use components (Pedišić 2017). From the public health perspective it may be important to know whether time spent sitting is replaced with quiet standing, physical activity or some other movement or non-movement related behaviour.

In the protocol we stated that in cases where we would include more than one comparison from a trial with multiple arms in the same meta-analysis, we would halve the numbers of control group participants to prevent them from being included twice, however this does not work for the inverse variance input method. One study, Neuhaus 2014a, reported only the results from ANCOVA and could not provide us with the raw data. For this trial we modelled the means and standard deviations from the intervention and the control group in Review Manager as closely to the real data as possible to achieve the same MD and standard error. Then we halved the number of participants in the control group and entered the resulting standard errors into Review Manager.

We judged studies to be at low risk of selective outcome reporting if the final publications of the trial reported what had been planned and registered in international databases (trial registries), such as ClinicalTrials.gov, Australia New Zealand Clinical Trials Registry (ANZCTR.org.au), Netherland’s Trial Registry (NTR). We judged the studies that were not registered in trial registries as being at low risk for selective outcome reporting if they reported all the outcomes mentioned in the methods section.

Initially, we planned to pool interventions that were categorised under broad headings like physical changes in workplace environment, workplace policy changes and information and counselling, but later we found that the interventions were quite different from one another and decided not to combine them under these broad headings. We also added a new category consisting of approaches that used multiple types of interventions at the same time. Due to the large number of outcomes it was not practical to incorporate a GRADE rating of the quality of the evidence of every single result. Hence we report time spent sitting at work and time spent in sitting bouts lasting 30 minutes or more for short-term follow-up in the ‘Summary of findings’ table. Where studies reporting effects at short-term follow-up for the above-mentioned outcomes were not available, we present medium-term follow-up. We only report the most relevant comparisons.

We also calculated a prediction interval for the outcome ‘sitting time at work’ for interventions comparing the effectiveness of sit-stand desks and sit-desks.
