Representation of Uncertain Multi-Channel Digital Signal Spaces and Study of Pattern Recognition Based on Metrics and Difference Values on Fuzzy $n$–cell Number Spaces

Guixiang Wang, Peng Shi, Senior Member, IEEE, and Paul Messenger

Abstract—In this paper, we discuss the problem of characterization for uncertain multi-channel digital signal spaces, propose using fuzzy $n$–cell number space to represent uncertain $n$–channel digital signal space, and put forward a method of constructing such fuzzy $n$–cell numbers. We introduce two new metrics and concepts of certain types of difference values on fuzzy $n$–cell number space, and study their properties. Further, based on the metrics or difference values appropriately defined we put forward an algorithmic version of pattern recognition in an imprecise or uncertain environment, and we also give practical examples to show the application and rationality of the proposed techniques.

Index Terms—Uncertain multi-channel digital signals, Fuzzy $n$–cell numbers, $n$–dimensional fuzzy vectors, Metrics, Difference values, Pattern recognition

I. INTRODUCTION

It is known that in a precise or certain environment, multi-channel digital signals can be represented by elements of multi-dimensional Euclidean space, i.e., crisp multi-dimensional vectors. If however we wish to study multi-channel digital signals in an imprecise or uncertain environment, then the signals themselves are imprecise or have no certain bound, and it becomes unwise to use crisp multidimensional vectors to represent them. In this paper, we recommend using fuzzy $n$–cell numbers to represent imprecise or uncertain multi-channel digital signals, and put forward a method of constructing such fuzzy $n$–cell numbers.

The concept of general fuzzy numbers was introduced by Chang and Zadeh [2] in 1972 with the consideration of the properties of probability functions. Since then both the numbers and the problems in relation to them (see for example [3, 4, 5, 6, 11, 16, 19, 20, 21]) have been widely studied. With the development of theories and applications of fuzzy numbers, this concept becomes more and more important. In [7] Kaleva ever used a special type of $n$–dimensional fuzzy number, whose sets of cuts are all hyper-rectangles. In 2002 we carefully studied the special type of $n$–dimensional fuzzy number, and call it fuzzy $n$–cell number in [14,15]. It has been demonstrated that fuzzy $n$–cell number is used much more conveniently than general $n$–dimensional fuzzy numbers in theoretical investigations and some fields of application in [14, 15, 17]. On the other hand, $n$–dimensional fuzzy vector is also an important concept, which is the Cartesian product of $n$ 1–dimensional fuzzy numbers. In 1985, Kaufmann and Gupta [8] already studied fuzzy vectors, soon afterwards, Miyakawa and Nakamura et al. [9,10,12] also studied the problems of theories and applications in relating to fuzzy vectors. In 1997, Butnariu [1] studied Methods of solving optimization problems and linear equations in the space of fuzzy vectors. Recently, we [14] showed that fuzzy $n$–cell numbers and $n$–dimensional fuzzy vectors can represent each other, and obtained the representations of the joint membership function and the edge membership functions of a fuzzy $n$–cell number of each other.

In a previous paper [15], we defined a metric $D_L$ on the fuzzy $n$–cell number space, and studied its properties. And in paper [14], we again studied this type of metric in regard to two fuzzy $n$–cell numbers as the form of $n$–dimensional fuzzy vectors. Although metric $D_L$ can be more conveniently used in applications and theoretical investigations, it has some shortcomings. That is, it has a tendency to be rougher, and can not really characterize the degree of difference of two fuzzy $n$–cell numbers in some applications (see Example 3.1 in Section 3 of this paper). In this paper, in order to discuss the problem of pattern recognition in an imprecise or uncertain environment based on degree of difference, we define two new metrics and some concepts of difference values on fuzzy $n$–cell number space, which may better characterize the
degree of difference of two fuzzy \( n \)-cell numbers in some applications, and study their properties.

It is well known that pattern recognition is an important field of research. In this aspect many research achievements have been obtained (for example, see [13]). In this paper, as applications of the metrics and difference values (defined by us), we also study the problem of pattern recognition in an imprecise or uncertain environment, put forward an algorithmic version of pattern recognition based on the metrics or difference values (defined by us) of fuzzy \( n \)-cell numbers, and also give examples to show the application and rationality of the method.

The organization of the paper is as follows. In Section 2, we give an example to show how to set up fuzzy \( n \)-cell numbers to represent imprecise or uncertain multi-channel digital signals. In Section 3, we define two new metrics, and study their properties. In Section 4, we introduce concepts of difference values of two fuzzy \( n \)-cell numbers, and examine their properties. In Section 5, an algorithmic version of pattern recognition is given based on the metrics or the difference values defined by us, and examples are also given to show the application and rationality of the method. Finally, in Section 6, we give a brief conclusion of this paper.

II. REPRESENTATIONS OF UNCERTAIN MULTI-CHANNEL DIGITAL SIGNALS

A fuzzy set of the Euclidean space \( \mathbb{R}^n \) is a function \( u: \mathbb{R}^n \to [0,1] \). For fuzzy set \( u \), we denote \([u]^* = \{x \in \mathbb{R}^n : u(x) \geq r \}\) for \( r \in [0,1] \), and \([u]^0 = \{x \in \mathbb{R}^n : u(x) > 0\}\) (the closure of \( \{x \in \mathbb{R}^n : u(x) > 0\} \)). If \( u \) is a normal and fuzzy convex fuzzy set of \( \mathbb{R}^n \), \( u(x) \) is upper semi-continuous, and \([u]^0\) is compact, then we call \( u \) a \( n \)-dimensional fuzzy numbers, and denote the \( n \)-dimensional fuzzy number space by \( E^n \). If \( u \in E \), and for each \( r \in [0,1] \), \([u]^r\) is a hyper rectangle, i.e., there exist \( u_r(l) = [u_r(l), u_r(u)] \), \( \{i = 1,2,\ldots,n\} \) such that \([u]^r = \prod_{i=1}^{n}[u_r(l), u_r(u)]\), then we call \( u \) a fuzzy \( n \)-cell number, and denote the fuzzy \( n \)-cell number space by \( L(E^n) \). A \( n \)-dimensional fuzzy vector is an ordered class \( (u_1, u_2, \ldots, u_n) \), where \( u_i \in E \) (i.e., \( E^1 \)), \( i = 1,2,\ldots,n \). In [14], we have shown that fuzzy \( n \)-cell numbers and \( n \)-dimensional fuzzy vectors can represent each other, and as the representation is unique, \( L(E^n) \) and the \( n \)-dimensional fuzzy vector space (i.e., the Cartesian product \( E \times E \times \cdots \times E \)) may be regarded as identical.

When exploring and discussing some quantity, properties or laws of movement of phenomena/objects in the physical world, it is essential for us to establish the description space of them. For instance, when the quantity in question is only the one with a single factor, we can take it as a dot in real number field \( \mathbb{R} \), that is, the space of quantities corresponding to single factor can be described by \( 1 \)-dimensional Euclidean space \( \mathbb{R} \). Similarly, we can describe the quantities with \( n \) factors, using \( n \)-dimensional Euclidean space \( \mathbb{R}^n \). However, in the physical world, many phenomena are imprecise or uncertain (such as, have no certain bound). When the quantity discussed by us possesses some imprecise or uncertain attributes, it is unsuitable that we use still \( \mathbb{R}^n \) to represent the space of the quantities (see Remark 2.1). It is our opinion that using the fuzzy \( n \)-cell number space discussed in [14, 15] to describe the quantities with some uncertain factors and discuss these quantities in this \( n \)-dimensional fuzzy vector space is a more suitable method to reveal the objective laws of things in physical world (see Remark 2.1).

In the following example, we demonstrate how we construct a fuzzy \( n \)-cell number to represent a quantity that possesses some uncertain attributes based on statistical data. About the algorithmic version of such fuzzy \( n \)-cell numbers, we can see the first or second step of the algorithmic version in Section 5.

Example 2.1. It is well known that different kinds of terrain or landcover possess the different reflections of the electromagnetic spectrum. Based on this principle, one can set up a method to recognize the category of landcover, a challenging remote sensing classification problem, using spectral and terrain features for vegetation classification in some zone. In remote sensing classification, the coligation of all species covering a zone of 4500 m² can be boiled down to an element of remote sensing space. We use “Korean Pine accounts for the main part” to denote forest that mainly contains Korean Pines. Because in different “Korean Pine accounts for the main part” areas, there are many different factors such as the difference of the density of Korean Pines, of the species and quantity of other plants, of the physiognomy and so on, the values of reflections of the electromagnetic spectrum are also different. Therefore “Korean Pine accounts for the main part” should not be a certain crisp value but a fuzzy set without certain bound. So, using a fuzzy number to represent the spectral sensitivity level of the “Korean Pine accounts for the main part” is more suitable than using a crisp number. Suppose that we use 4 wave bands: MSS-4, MSS-5, MSS-6, MSS-7. We take 10 samples, and acquire the following data for some zone of “Korean Pine accounts for the main part”:

<table>
<thead>
<tr>
<th>Sample</th>

</tbody>
</table>

We can directly work out the following means \( \mu_i \), \( (i=1,2,3,4) \) and standard deviations \( \sigma_i \), \( (i=1,2,3,4) \) from the data:
MSS-4  MSS-5  MSS-6  MSS-7
\(\mu_i = 15.46\)  \(\mu_2 = 12.58\)  \(\mu_i = 36.54\)  \(\mu_4 = 17.33\)
\(\sigma_i = 1.22\)  \(\sigma_1 = 0.88\)  \(\sigma_3 = 3.55\)  \(\sigma_4 = 2.08\)

From the means and the standard deviations, with

\[ u_i(x_i) = \begin{cases} 
\frac{x_i - (\mu_i - 2\sigma_i)}{2\sigma_i} & \text{if } x_i \in [\mu_i - 2\sigma_i, \mu_i] \cap (0, +\infty) \\
\frac{(\mu_i + 2\sigma_i) - x_i}{2\sigma_i} & \text{if } x_i \in (\mu_i + 2\sigma_i, \mu_i] \cap (0, +\infty) \\
0 & \text{if } x_i \notin [\mu_i - 2\sigma_i, \mu_i + 2\sigma_i] \cap (0, +\infty) 
\end{cases} \]

we can define 4 triangular model one-dimensional fuzzy numbers \(u_i\), \(u_2\), \(u_3\) and \(u_4\) that respectively correspond with MSS-4, MSS-5, MSS-6 and MSS-7:

\[ u_1(x_1) = \begin{cases} 
\frac{x_1 - 13.02}{17.9 - x_1} & \text{if } x_1 \in [13.02, 15.46] \\
0 & \text{if } x_1 \notin (13.02, 15.46) 
\end{cases} \]
\[ u_2(x_2) = \begin{cases} 
\frac{x_2 - 10.82}{14.34 - x_2} & \text{if } x_2 \in [10.82, 12.58] \\
0 & \text{if } x_2 \notin (10.82, 12.58) 
\end{cases} \]
\[ u_3(x_3) = \begin{cases} 
\frac{x_3 - 29.44}{43.64 - x_3} & \text{if } x_3 \in [29.44, 36.54] \\
0 & \text{if } x_3 \notin (29.44, 36.54) 
\end{cases} \]
\[ u_4(x_4) = \begin{cases} 
\frac{x_4 - 13.17}{21.49 - x_4} & \text{if } x_4 \in [13.17, 17.33] \\
0 & \text{if } x_4 \notin (13.17, 17.33) 
\end{cases} \]

By Theorem 3.1 and 3.2 in [14], we know that \(u_1\), \(u_2\), \(u_3\) and \(u_4\) determine a fuzzy 4-cell number \(u = (u_1, u_2, u_3, u_4)\), and the membership function of \(u\)

\[ u(x_1, x_2, x_3, x_4) = \min\{u_i(x_i), u_2(x_2), u_3(x_3), u_4(x_4)\} \]

\((x_1, x_2, x_3, x_4) \in R^4\)

Then \(u\) can be used to represent “Korean Pine accounts for the main part”.

Likewise, from the means and the standard deviations, according to

\[ v_i(x_i) = \begin{cases} 
\exp\left(-\frac{(x_i - \mu_i)^2}{2\sigma_i^2}\right) & \text{if } x_i \in (0, +\infty) \\
0 & \text{if } x_i \notin (0, +\infty) 
\end{cases} \]

we can also define 4 Gaussian model one-dimensional fuzzy numbers \(v_1\), \(v_2\), \(v_3\) and \(v_4\) that respectively correspond with MSS-4, MSS-5, MSS-6 and MSS-7:

\[ v_1(x_1) = \exp\left(-\frac{(x_1 - 15.46)^2}{2.98}\right) \quad \text{if } x_1 \in (0, +\infty) \]
\[ v_2(x_2) = \exp\left(-\frac{(x_2 - 12.58)^2}{1.56}\right) \quad \text{if } x_2 \in (0, +\infty) \]
\[ v_3(x_3) = \exp\left(-\frac{(x_3 - 36.54)^2}{25.21}\right) \quad \text{if } x_3 \in (0, +\infty) \]
\[ v_4(x_4) = \exp\left(-\frac{(x_4 - 17.33)^2}{8.65}\right) \quad \text{if } x_4 \in (0, +\infty) \]

and obtain the membership function of the fuzzy 4-cell number \(v = (v_1, v_2, v_3, v_4)\) determined by \(v_1\), \(v_2\), \(v_3\) and \(v_4\) as

\[ v(x_1, x_2, x_3, x_4) = \min\{v_1(x_1), v_2(x_2), v_3(x_3), v_4(x_4)\} \]

\((x_1, x_2, x_3, x_4) \in R^4\). Then the fuzzy 4-cell number \(v\) can also be used to represent the “Korean Pine accounts for the main part”.

Remark 2.1. Of course, if the quantity to describe is precise and certain, we should use a crisp multi-dimensional vector to represent it. However, if the quantity to describe is imprecise and uncertain, such as “Korean Pine accounts for the main part”, then using a fuzzy \(n\)-cell number to represent it is better than using a crisp \(n\)-dimensional vector. If we narrowly use a crisp multi-dimensional vector, such as \((15.46, 12.58, 36.54, 17.33)\) (i.e., the mean vector), to represent “Korean Pine accounts for the main part”, then it can not clearly tell us the relationship of “Korean Pine accounts for the main part” and the zone whose value of reflection of electromagnetic spectrum is \((15.16, 12.80, 37.50, 16.79)\) since \((15.16, 12.80, 37.50, 16.79) \neq (15.46, 12.58, 36.54, 17.33)\). If we use fuzzy \(n\)-cell number \(v = (v_1, v_2, v_3, v_4)\) to represent it, then we can almost affirm that the zone whose value is \((15.16, 12.80, 37.50, 16.79)\) is part of “Korean Pine accounts for the main part” since \(v(15.16, 12.80, 37.50, 16.79) = \min(0.94, 0.94, 0.93, 0.93) = 0.93\), i.e., the degree of the zone which is “Korean Pine accounts for the main part” is 0.93.

III. METRICS ON FUZZY \(n\)-CELL NUMBER SPACE

In [3], the authors studied the metric \(d_p(\cdot, \cdot)\) (note that in this paper we rewrite \(d_p(\cdot, \cdot)\) as \(D_p(\cdot, \cdot)\)) on general \(n\)-dimensional fuzzy number space \(E^n\), which is defined by

\[ D_p(u, v) = \left(\int_0^1 d\left([u']^i, [v']^i\right)\right)^{\frac{1}{p}} \]

for any \(u, v \in E^n\), and point out that the metric \(D_p\) is complete.

In [15], we studied the metrics \(D\) and \(D_L\) on \(L(E^n)\), but the two metrics seem to be ‘rough’ in certain applications (see Example 3.1). In the following, other metrics are defined on \(L(E^n)\), which better reveal the difference between two different uncertain quantities (see Example 3.1). Their properties are also discussed such that they may be used appropriately.
We denote $LC(R^n) = \{A : \text{there exist } a_i \leq b_i, i = 1,2,\cdots,n\}$ such that $A = \prod_{i=1}^n[a_i,b_i]$ , where $\prod_{i=1}^n[a_i,b_i]$ is the Cartesian product $[a_1,b_1] \times [a_2, b_2] \times \cdots \times [a_n, b_n]$.

**Theorem 3.1.** We define mappings $\hat{d}_a : LC(R^n) \times LC(R^n) \rightarrow [0, +\infty)$ and $\widehat{d}_a : LC(R^n) \times LC(R^n) \rightarrow [0, +\infty)$ by

$$
\hat{d}_a(A,B) = \sum_\alpha \alpha \cdot \max \{|a_i-b_i|, |\bar{a}_i-\bar{b}_i|\}
$$

and

$$
\widehat{d}_a(A,B) = \sum_\alpha \alpha \cdot \frac{|a_i-b_i| + |\bar{a}_i-\bar{b}_i|}{2}
$$

for any $A = \prod_{i=1}^n[a_i,\bar{a}_i] \in LC(R^n)$ and $B = \prod_{i=1}^n[b_i,\bar{b}_i] \in LC(R^n)$, where $\alpha = (\alpha_1,\alpha_2,\cdots,\alpha_n)$ satisfies $\sum_\alpha \alpha = 1$ and $\alpha_i \geq 0$, $i = 1,2,\cdots, n$. Then for any $A = \prod_{i=1}^n[a_i,\bar{a}_i], B = \prod_{i=1}^n[b_i,\bar{b}_i], C = \prod_{i=1}^n[c_i,\bar{c}_i]$ in $LC(R^n)$ and each $k \in R$, $\hat{d}_a$ and $\widehat{d}_a$ satisfies

1. $\hat{d}_a(A,B) = \hat{d}_a(B,A)$ and $\widehat{d}_a(A,B) = \widehat{d}_a(B,A)$;
2. $\hat{d}_a(A,B) \geq 0$ and $\widehat{d}_a(A,B) \geq 0$;
3. $\hat{d}_a(A,0) = 0 \Leftrightarrow A = 0 \Leftrightarrow \widehat{d}_a(A,0) = 0$;
4. $\hat{d}_a(A,C) + \hat{d}_a(C,B)$ and $\widehat{d}_a(A,B) \leq \hat{d}_a(A, C) + \hat{d}_a(C,B)$;
5. $\hat{d}_a(A+C, B+C) = \hat{d}_a(A, B)$ and $\hat{d}_a(A+C, B+C) = \widehat{d}_a(A, B)$;
6. $\hat{d}_a(kA,kB) = k \hat{d}_a(A,B)$ and $\hat{d}_a(kA,kB) = k \hat{d}_a(A,B)$.

**Proof.** We only show Proofs (4), (5) and (6) (the other proofs are easy). From $\hat{d}_a(A,B) = \sum_\alpha \alpha \cdot \max \{|a_i-b_i|, |\bar{a}_i-\bar{b}_i|\}$

$$
\leq \sum_\alpha \alpha \cdot \max \{|a_i-c_i| + |c_i-b_i|, |\bar{a}_i-\bar{c}_i| + |\bar{c}_i-\bar{b}_i|\}
$$

$$
\leq \sum_\alpha \alpha \cdot \max \{|a_i-c_i|, a_i-c_i| + max\{|c_i-b_i|, |\bar{c}_i-\bar{b}_i|\}\}
$$

$$
= \hat{d}_a(A,C) + \hat{d}_a(C,B)
$$

$$
\hat{d}_a(A+C, B+C) = \sum_\alpha \alpha \cdot \max \{|a_i+c_i-b_i+c_i|, |a_i+c_i-b_i+c_i|\}
$$

$$
= \sum_\alpha \alpha \cdot \max \{|a_i+c_i-b_i+c_i|, a_i-\bar{c}_i| + max\{|c_i-b_i|, |\bar{c}_i-\bar{b}_i|\}\}
$$

$$
= \hat{d}_a(A,B)
$$

$$
\hat{d}_a(kA,kB) = \sum_\alpha \alpha \cdot \max \{|ka_i-kb_i|, |ka_i-kb_i|\}
$$

$$
= \sum_\alpha \alpha \cdot \max \{|ka_i-kb_i|, k|a_i-\bar{b}_i|\}
$$

$$
= k \hat{d}_a(A,B)
$$

we see that (4), (5) and (6) of the theorem hold for $\hat{d}_a$. For $\widehat{d}_a$, we can similarly prove that (4), (5) and (6) of the theorem also hold.

**Theorem 3.2.** We define mappings $\hat{D}_{a,u,v} : L(E^n) \times L(E^n) \rightarrow [0, +\infty)$ and $\widehat{D}_{a,u,v} : L(E^n) \times L(E^n) \rightarrow [0, +\infty)$ by

$$
\hat{D}_{a,u,v}(u,v) = \left(\int_0^1 \|r \cdot \hat{d}_a([u^r],[v^r])\| \, dr\right)^{1/p}
$$

and

$$
\widehat{D}_{a,u,v}(u,v) = \left(\int_0^1 \|r \cdot \widehat{d}_a([u^r],[v^r])\| \, dr\right)^{1/p}
$$

i.e.,

$$
\hat{D}_{a,u,v}(u,v) = \left(\int_0^1 \sum_{i=1}^n \alpha_i \cdot \max \{|u_i(r)-v_i(r)|, |u_i(r)-\bar{v}_i(r)|\} \, dr\right)^{1/p}
$$

and

$$
\widehat{D}_{a,u,v}(u,v) = \left(\int_0^1 \sum_{i=1}^n \alpha_i \cdot \|u_i(r)-v_i(r)\| \, dr\right)^{1/p}
$$

for any $(u,v) \in L(E^n) \times L(E^n)$, where $p \geq 1$ and $\alpha = (\alpha_1,\alpha_2,\cdots,\alpha_n)$ satisfies $\sum_\alpha \alpha = 1$ and $\alpha > 0$, $i = 1,2,\cdots, n$. Then for any $u,v,w \in L(E^n)$ and each $k \in R$, $\hat{D}_{a,u,v}$ and $\widehat{D}_{a,u,v}$ satisfy

1. $\hat{D}_{a,u,v}(u,v) = \hat{D}_{a,u,v}(v,u)$ and $\hat{D}_{a,u,v}(u,v) = \hat{D}_{a,v,u}(v,u)$;
2. $\hat{D}_{a,u,v}(u,v) \geq 0$ and $\hat{D}_{a,u,v}(u,v) \geq 0$;
3. $\hat{D}_{a,u,v}(v,0) = u \Leftrightarrow u = v \Leftrightarrow \hat{D}_{a,u,v}(u,0) = 0$;
4. $\hat{D}_{a,u,v}(u,v) \leq \hat{D}_{a,u,v}(u,w) + \hat{D}_{a,u,v}(w,v)$ and $\hat{D}_{a,u,v}(u,v) \leq \hat{D}_{a,u,v}(u,w) + \hat{D}_{a,u,v}(w,v)$;
5. $\hat{D}_{a,u,v}(u+w,v+w) = \hat{D}_{a,u,v}(u,v)$ and $\hat{D}_{a,u,v}(u+w,v+w) = \hat{D}_{a,u,v}(v,u)$;
6. $\hat{D}_{a,u,v}(ku,kv) = k \cdot \hat{D}_{a,u,v}(u,v)$ and $\hat{D}_{a,u,v}(ku,kv) = k \cdot \hat{D}_{a,u,v}(u,v)$.

**Proof.** It is obvious that (1) and (2) of the theorem hold. By the definition of $\hat{D}_{a,u,v}$, it is obvious that $u = v \Rightarrow \hat{D}_{a,u,v}(u,v) = 0$ . Otherwise, let $\hat{D}_{a,u,v}(u,v) = 0$ . Then we have $\int_0^1 \sum_{i=1}^n \alpha_i \cdot \max \{|u_i(r)-v_i(r)|, |u_i(r)-\bar{v}_i(r)|\} \, dr = 0$ . Taking note of $\alpha > 0$, we see that $r(\sum_{i=1}^n \alpha_i \cdot \max \{|u_i(r)-v_i(r)|, |u_i(r)-\bar{v}_i(r)|\} = 0$ holds for $r$ almost everywhere on $[0,1]$. Further, we have that $\sum_{i=1}^n \alpha_i \cdot \max \{|u_i(r)-v_i(r)|, |u_i(r)-\bar{v}_i(r)|\} = 0$ holds for $r$ almost everywhere on $[0,1]$, so we can see that $u_i(r)=v_i(r)$ and $u_i(r)=\bar{v}_i(r)$ holds for $r$ almost everywhere on $[0,1]$ for $i = 1,2,\cdots, n$. Therefore, we obtain that $[u^r]=[v^r]$ holds for $r$ almost everywhere on $[0,1]$, so we know that $u=v$ holds by Lemma 2.1 in [18]. Thus, $\hat{D}_{a,u,v}(u,v) = 0 \Leftrightarrow u = v$ holds. Likewise, we can prove...
The proofs of $\tilde{D}_{a,p}(u,v) \leq \tilde{D}_{a,p}(u,w)+\tilde{D}_{a,p}(w,v)$, (5) and (6) can be similarly proved.

Remark 3.1. From Theorems 3.1 and 3.2, we know $\tilde{d}_a,\tilde{d}_{a,p}$ and $\tilde{D}_{a,p},\tilde{D}_{a,p}$ are metrics on LC($R^n$) and LC($E^n$), respectively, and satisfy translation invariance, absolute homogeneity. Also, from the factor $r$ of the integrands in the definitions of $\tilde{D}_{a,p}(u,v)$ and $\tilde{D}_{a,p}(u,v)$, we can see that the bigger the degrees of the points are, which belong to the fuzzy $n$-cell numbers $u$ and $v$, the greater the effects on the metric of $u$ and $v$. This is true in reality.

Example 3.1. Let $u,v,w$ be the 2-cell numbers defined by: $u=(u_1,u_2), v=(v_1,v_2)$ and $w=(w_1,w_2)$, where,

$$u_i(x) = \begin{cases} x & \text{if } x \in [0,1] \\ 2-x & \text{if } x \in \{1,2\} \\ 0 & \text{if } x \in \{2,3\} \\ \end{cases}, \quad i=1,2$$

$$w_i(x) = \begin{cases} x & \text{if } x \in [0,1] \\ 2-x & \text{if } x \in \{1,2\} \\ 0 & \text{if } x \in \{2,3\} \\ \end{cases}, \quad i=1,2$$

Then we know that $u_i(r)=r$, $v_i(r)=2-r$, $v_i(r)=2+r$, $v_i(r)=4-r$ ( $i=1,2$ ), $w_i(r)=r$, $w_i(r)=2-r$, $w_i(r)=2+r$ and $w_i(r)=4-r$ for $r \in [0,1]$. From the definitions of $D_L$, we have $D_L(u,v)=2=D_L(u,w)$, i.e., $D_L$ can not tell us the difference of $D_L(u,v)$ and $D_L(u,w)$, so we say that $D_L$ seems to be ‘rough’ (similar proof for $D_P$). However, as a matter of fact, $D_L(u,v)$ and $D_L(u,w)$ should have some difference.

Taking $\alpha=(1/2,1/2)$, from the definitions of $\tilde{D}_{a,p}$, we can obtain $\tilde{D}_{a,p}(u,v) \geq \frac{2}{(1+p)^{1/p}} \geq \frac{1}{(1+p)^{1/p}} = \tilde{D}_{a,p}(u,w)$, this accord with fact.

If we restrain the metric $D_P$ (i.e. $d_a(\cdot,\cdot)$) defined by Diamond in [3], see paragraph 1 of this section) on general $n$-dimensional fuzzy numeric space $E^n$ into on LC($E^n$), then it also becomes a metric on L($E^n$). In the following, we give the relationships of the metrics $\tilde{D}_{a,p},\tilde{D}_{a,p}$ and $D_P$.

Theorem 3.3. Metrics $\tilde{D}_{a,p},\tilde{D}_{a,p}$ and $D_P$ satisfy

(1) $\frac{1}{2} \tilde{D}_{a,p} \leq \tilde{D}_{a,p} \leq D_L \leq D_P$, i.e., $\frac{1}{2} \tilde{D}_{a,p}(u,v) \leq \tilde{D}_{a,p}(u,v) \leq D_L(u,v) \leq D_P(u,v)$ for any $u,v \in L(E^n)$ ( $D$ is discussed in [15]).

(2) $\tilde{D}_{a,p} \leq \frac{1}{(p+1)^{1/p}} D_L \leq \frac{1}{(p+1)^{1/p}} D_P$, i.e., $\tilde{D}_{a,p}(u,v) \leq D_L(u,v) \leq D_P(u,v)$ for any $u,v \in L(E^n)$.

Proof. For any $u,v \in L(E^n)$ and $r \in [0,1]$, by the definitions of $\tilde{d}_a$ and $\tilde{d}_{a,p}$, we have

$$\frac{1}{2} \tilde{d}_a([u^o],[v^o]) = \frac{1}{2} \sum_i \alpha_i \max \{ |u_i(r)-v_i(r)|, |\overline{u_i}(r)-\overline{v_i}(r)| \} \leq \frac{1}{2} \sum_i \alpha_i \max \{ |u_i(r)-v_i(r)|, |\overline{u_i}(r)-\overline{v_i}(r)| \} \leq \sum_i \alpha_i \max \{ |u_i(r)-v_i(r)|, |\overline{u_i}(r)-\overline{v_i}(r)| \} \leq \sum_i \alpha_i \max \{ |u_i(r)-v_i(r)|, |\overline{u_i}(r)-\overline{v_i}(r)| \} \leq \sum_i \alpha_i \max \{ |u_i(r)-v_i(r)|, |\overline{u_i}(r)-\overline{v_i}(r)| \} \leq \frac{1}{2} \tilde{d}_a([u^o],[v^o])$$

From (3), we can directly obtain $\frac{1}{2} \tilde{D}_{a,p}(u,v) \leq \tilde{D}_{a,p}(u,v) \leq D_L(u,v) \leq D_P(u,v)$.

By Theorem 4.4 in [15], we know $d_L \leq d \leq \sqrt{n}d_L$, where,

$$d_L(A,B) = \max \{ |a_i-b_i|, |\overline{a}_i-\overline{b}_i| \}$$

for any $A=\prod_{i=1}^n |\overline{a}_i|\overline{a}_i$ and $B=\prod_{i=1}^n |\overline{b}_i|\overline{b}_i \in LC(R^n)$. Therefore, for any $u,v \in L(E^n)$, we have

$$\tilde{D}_{a,p}(u,v) = \left( \int \left[ \sum_{i=1}^n \alpha_i \max \{ |u_i(r)-v_i(r)|, |\overline{u_i}(r)-\overline{v_i}(r)| \} \right] dr \right)^{1/p} \leq \left( \int \left[ \sum_{i=1}^n \alpha_i \max \{ |u_i(r)-v_i(r)|, |\overline{u_i}(r)-\overline{v_i}(r)| \} \right] dr \right)^{1/p} \leq \left( \int \left[ d([u^o],[v^o]) \right] dr \right)^{1/p} \leq \left( \int \left[ D(u,v) \right] dr \right)^{1/p}$$

Thus, we also obtain $\tilde{D}_{a,p}(u,v) \leq D_P(u,v) \leq D(u,v)$ and the proof of (1) of the theorem is complete.

From

$$\tilde{D}_{a,p}(u,v) = \left( \int \left[ \sum_{i=1}^n \alpha_i \max \{ |u_i(r)-v_i(r)|, |\overline{u_i}(r)-\overline{v_i}(r)| \} \right] dr \right)^{1/p} \leq \left( \int \left[ D(u,v) \right] dr \right)^{1/p}$$
\begin{align*}
\leq \left( \int_0^1 [r \cdot d_L([u],[v])]^p \right)^{1/p} \\
\leq \left( \int_0^1 [r \cdot \sup_{\alpha \in [0,1]} d_L([u],[v])]^p \right)^{1/p} \\
= \left( \int_0^1 [r \Delta_L(u,v)]^p \right)^{1/p} \\
\leq D(u,v) \left( \int_0^1 p^\alpha \, dr \right)^{1/p} \\
= \frac{1}{(p+1)^{1/p}} D(u,v)
\end{align*}
and Theorem 4.5 in [15], we can see that (2) of the theorem holds.

\textbf{Remark 3.2.} From (1) of Theorem 3.3, we see
\[ \frac{1}{2} \hat{D}_{u,\alpha} \leq \hat{D}_{u,\beta} \leq \frac{1}{2} \hat{D}_{u,\alpha} \], i.e., \( \hat{D}_{u,\alpha} \) and \( \hat{D}_{u,\beta} \) are equivalent, so we know that \( \hat{D}_{u,\alpha} \) and \( \hat{D}_{u,\beta} \) induce equivalent topologies on \( L(E^\alpha) \) by the knowledge of topological space.

\section{Difference Values on Fuzzy n-Cell Number Space}

In Section 3, we discussed metrics on \( L(E^\alpha) \). But sometimes these have some shortcomings demonstrating the difference of two objects. For example, we consider that the degree of difference of 1 and 2 is bigger than the degree of difference of 10\(^{10}\) and 10\(^{10}+1\) though their metrics (Euclidean metric) measure both are 1. A mapping from the Cartesian product \( X \times X \) of a set \( X \) into \( R \) needs to satisfy stronger conditions in order that it can become a metric, and this brings limitations in some applications. The measure used to characterize the differences does not need to satisfy all metric conditions, for example, when we set up a method of pattern recognition basing on the principle of minimal difference (i.e. the principle of maximal likelihood), the measure used to characterize the differences does not need to satisfy all metric conditions. To conveniently set up methods of pattern recognition using fuzzy \( n \)-cell numbers, we introduce the concepts of difference values on \( L(E^\alpha) \), and study the properties.

Let \( u \in L(E^\alpha) \) and \( \alpha = (\alpha_1,\alpha_2,\cdots,\alpha_n) \in R^n \) satisfy
\[ \sum_{i=1}^n \alpha_i = 1 \quad \text{and} \quad \alpha_i \geq 0 \quad ( i=1,2,\cdots,n ) \]. We denote
\[ M_s(u) = \sum_{i=1}^n \alpha_i \int_0^1 r \left[ u(r) + v(r) \right] \, dr \],
denote \( M(u) = M_s(u) \) as \( \alpha = (\frac{1}{n},\frac{1}{n},\cdots,\frac{1}{n}) \), and denote \( M(u) = M_s(u) \) as \( u \in E \).

\textbf{Definition 4.1.} Let \( u,v \in L(E^\alpha) \) with
\[ M_s(u) \geq 0 \quad \text{and} \quad M_s(u) + M_s(v) \neq 0 \]. We denote
\[ L_{\alpha,s}(u,v) = \sum_{i=1}^n \alpha_i \int_0^1 r \left| u(r) - v(r) \right| \, dr \]
and
\[ R_{\alpha,s}(u,v) = \sum_{i=1}^n \alpha_i \int_0^1 r \left| u(r) - v(r) \right| \, dr \]
and call \( L_{\alpha,s}(u,v) \) and \( R_{\alpha,s}(u,v) \) a left difference value and a right difference value of \( u \) and \( v \) (with respect to the weight \( \alpha \) and parameter \( a \)), respectively. And we denote
\[ \Delta_{\alpha,s}(u,v) = \frac{1}{2} \left[ L_{\alpha,s}(u,v) + R_{\alpha,s}(u,v) \right] \]
i.e.,
\[ \Delta_{\alpha,s}(u,v) = \sum_{i=1}^n \alpha_i \int_0^1 r \left| u(r) - v(r) \right| + \left| u(r) - v(r) \right| \, dr \]
and call \( \Delta_{\alpha,s}(u,v) \) a difference value of \( u \) and \( v \) (with respect to the weight \( \alpha \) and parameter \( a \)), where,
\[ \alpha = (\alpha_1,\alpha_2,\cdots,\alpha_n) \in R^n \] with \( \sum_{i=1}^n \alpha_i = 1 \) and \( \alpha \geq 0 \)
\[ ( i = 1,2,\cdots,n ) \], and \( a \in (0,\infty) \). Specially, we denote
\[ \Delta_s(u,v) = \Delta_{\alpha,s}(u,v) \]
as \( \alpha = (\frac{1}{n},\frac{1}{n},\cdots,\frac{1}{n}) \), and \( \Delta_s(u,v) \)
as \( \Delta_{\alpha,s}(u,v) \) as \( u,v \in E \).

\textbf{Remark 4.1.} (1) Generally speaking, we consider that the degree of the difference of two numbers is related not only by the metric of them but also by the sizes of them. As the metrics are the same, the bigger the sizes of the two numbers are, the smaller the degree of their difference is. The denominator \( |M_s(u)+M_s(v)| \) in the definition of \( \Delta_{\alpha,s} \) just plays the action (see Example 4.1), and the exponent \( a \) in \( [M_s(u)+M_s(v)]^a \) can be properly chosen accordingly to the case in question. (2) Taking the note of that \( \sum_{i=1}^n \alpha_i \left( \frac{M(u_i)+M(v_i)}{M_s(u)+M_s(v)} \right)^a = 1 \) holds as \( \alpha = (\frac{1}{n},\frac{1}{n},\cdots,\frac{1}{n}) \) and \( a = 1 \), and \( \sum_{i=1}^n \alpha_i \left( \frac{M(u_i)+M(v_i)}{M_s(u)+M_s(v)} \right)^a = 1 \)
does not necessarily hold as \( \alpha \neq (\frac{1}{n},\frac{1}{n},\cdots,\frac{1}{n}) \) or \( a \neq 1 \), from
\[ \Delta_{\alpha,s}(u,v) = \sum_{i=1}^n \alpha_i \int_0^1 r \left| u(r) - v(r) \right| + \left| u(r) - v(r) \right| \, dr \]
\[ \left( \sum_{i=1}^n \alpha_i \int_0^1 r \left| u(r) + v(r) \right| + \left| u(r) + v(r) \right| \, dr \right)^a \]
\[ = \sum_{i=1}^n \alpha_i \left( \int_0^1 r \left| u(r) + v(r) + u(r) + v(r) \right| \, dr \right)^a \]
\[ = \sum_{i=1}^n \alpha_i \left( \int_0^1 r \left| u(r) + v(r) + u(r) + v(r) \right| \, dr \right)^a \]
\[ = \sum_{i=1}^n \alpha_i \left( \int_0^1 r \left| u(r) + v(r) + u(r) + v(r) \right| \, dr \right)^a \]
\[ \Delta_s(u,v) \]
we can directly see that $\Delta(u,v)$ is a convex combination of

$$\Delta_i(u,v), \quad i=1,2,\cdots,n,$$

but $\Delta_{\alpha_\sigma}(u,v)$ is not necessarily a convex combination of $\Delta_i(u,v)$, $i=1,2,\cdots,n$ as $\alpha \neq \frac{1}{n}, \frac{1}{n}, \cdots, \frac{1}{n}$ or $a \neq 1$.

**Example 4.1.** Let $u,v,u',v'$ be the 2-cell numbers defined by: $u = (u_1,u_2), \quad v = (v_1,v_2), \quad u' = (u'_1,u'_2)$ and $v' = (v'_1,v'_2)$, where,

$$u_i(x_i) = \begin{cases} x_i & \text{if } x_i \in [0,1] \\ 2-x_i & \text{if } x_i \in (1,2) \\ 0 & \text{if } x_i \not\in [0,2] \end{cases}$$

$$v_i(x_i) = \begin{cases} -10+x_i & \text{if } x_i \in [0,11] \\ 12-x_i & \text{if } x_i \in (11,12] \\ 0 & \text{if } x_i \not\in [10,12] \end{cases}$$

$$u'_i(x_i) = \begin{cases} -100+x_i & \text{if } x_i \in [100,101] \\ 102-x_i & \text{if } x_i \in (101,102] \\ 0 & \text{if } x_i \not\in [100,102] \end{cases}$$

$$v'_i(x_i) = \begin{cases} -110+x_i & \text{if } x_i \in [0,11] \\ 112-x_i & \text{if } x_i \in (11,12] \\ 0 & \text{if } x_i \not\in [10,12] \end{cases}$$

and $i=1,2$. Then we know that $\bar{u}_i(r) = r$, $\bar{u}'_i(r) = 2-r$, $\bar{v}_i(r) = 10+r$, $\bar{v}'_i(r) = 12-r$, $\bar{u}'_i(r) = 100+r$, $\bar{u}(r) = 102-r$, $\bar{v}'(r) = 110+r$, $\bar{v}'(r) = 112-r$ ( $r \in [0,1], \quad i=1,2$ ). From the definitions of $\bar{D}_{\alpha_\sigma}$ and $\Delta_{\alpha_\sigma}$, we can obtain

$\bar{D}_{\alpha_\sigma}(u,v)$

$$= \frac{1}{2} \left[ \int_0^1 [r(\alpha_i(100+r-110-r)+|102-r-112+r|) \\ + \alpha_\sigma(100+r-110-r+|102-r-112+r|)] dr \right]^{1/p}$$

$$= \frac{1}{2} \left( \frac{20^p}{(1+p)} \right)^{1/p} \bar{D}_{\alpha_\sigma}(u',v')$$

$\Delta_{\alpha_\sigma}(u,v)$

$$= \alpha_\sigma \int_0^1 \left( \frac{100+r-110-r}{|102-r-112+r|} \right) dr + \alpha_\sigma \int_0^1 \left( \frac{100+r-110-r}{|102-r-112+r|} \right) dr$$

$$= \frac{10}{12} \Delta_{\alpha_\sigma}(u',v')$$

so we have $\bar{D}_{\alpha_\sigma}(u,v) = \bar{D}_{\alpha_\sigma}(u',v')$ and $\Delta_{\alpha_\sigma}(u,v) = \Delta_{\alpha_\sigma}(u',v')$.

**Property 4.1.** Let $u,v \in L(E^n)$ with $M_{\alpha}(u), \quad M_{\alpha}(v) \geq 0$ and $M_{\alpha}(u) + M_{\alpha}(v) \neq 0$, $\alpha = (\alpha_1,\alpha_2,\cdots,\alpha_n) \in R^n$ with $\sum_{i=1}^{n} \alpha_i = 1$ and $\alpha_i > 0$ ( $i=1,2,\cdots,n$ ), and $a \in (0,\infty)$. Then

1. $\Delta_{\alpha_\sigma}(u,v) \geq 0$;
2. $\Delta_{\alpha_\sigma}(u,v) = 0$ if and only if $u = v$;
3. $\Delta_{\alpha_\sigma}(u,v) = \Delta_{\alpha_\sigma}(v,u)$;
4. $\Delta_{\alpha_\sigma}(u,v) \geq \Delta_{\alpha_\sigma}(v,w)$ for any $w \in L(E^n)$ and $u \leq v \leq w$;
5. $\Delta_{\alpha_\sigma}(u+v+w+\cdots) \leq \Delta_{\alpha_\sigma}(u,v)$ for any $w \in L(E^n)$ and

$$w \geq \hat{0}, \hat{1}, \cdots, \hat{n};$$
6. $\Delta_{\alpha_\sigma}(ku,kv) = k^{-\sigma} \Delta_{\alpha_\sigma}(u,v)$ for any $k > 0$.

**Proof.** It is obvious that the conclusions (1) and (3) hold. The proof of conclusion (2) can also be completed by imitating the proof of (3) of Theorem 3.2 by using Lemma 2.1 in [18].

From $u \leq v \leq w$, we know that $u_i(r) \leq v_i(r) \leq w_i(r)$ and $\bar{u}_i(r) \leq \bar{v}_i(r) \leq \bar{w}_i(r)$ ( $i=1,2,\cdots,n$ ), so $|u_i(r)-w_i(r)| \geq |v_i(r)-w_i(r)|$ and $|\bar{u}_i(r)-\bar{w}_i(r)| \geq |\bar{v}_i(r)-\bar{w}_i(r)|$. Therefore, we have

$$\sum_{i=1}^{n} \alpha_i \int_0^1 \left| [u_i(r)-w_i(r)] + [\bar{u}_i(r)-\bar{w}_i(r)] \right| dr$$

$$\geq \sum_{i=1}^{n} \alpha_i \int_0^1 \left| [v_i(r)-w_i(r)] + [\bar{v}_i(r)-\bar{w}_i(r)] \right| dr$$

On the other hand, from $u_i(r) \leq v_i(r) \leq w_i(r)$ and $\bar{u}_i(r) \leq \bar{v}_i(r) \leq \bar{w}_i(r)$ ( $i=1,2,\cdots,n$ ), we can also see that $M_{\alpha}(u)$

$$= \sum_{i=1}^{n} \alpha_i \int_0^1 \left| [u_i(r)+\bar{u}_i(r)] \right| + \left| [\bar{v}_i(r)-\bar{w}_i(r)] \right| dr = M_{\alpha}(v),$$

so we can obtain $0 \leq M_{\alpha}(u) \leq M_{\alpha}(v) \leq M_{\alpha}(w)$. Thus, we have

$$\Delta_{\alpha_\sigma}(u,w) = \sum_{i=1}^{n} \alpha_i \int_0^1 \left| [u_i(r)-w_i(r)] + [\bar{u}_i(r)-\bar{w}_i(r)] \right| dr$$

$$\leq \sum_{i=1}^{n} \alpha_i \int_0^1 \left| [v_i(r)-w_i(r)] + [\bar{v}_i(r)-\bar{w}_i(r)] \right| dr$$

so conclusion (4) holds.

From $w \geq \hat{0}$, we know $M_{\alpha}(w) \geq 0$, so we have

$$\Delta_{\alpha_\sigma}(u+v+w+\cdots) \leq \Delta_{\alpha_\sigma}(u,v) \leq \Delta_{\alpha_\sigma}(u+w+v+\cdots)$$

$$\leq \Delta_{\alpha_\sigma}(u+w+v+\cdots) \leq \Delta_{\alpha_\sigma}(u,v) \leq \Delta_{\alpha_\sigma}(u+v+w+\cdots)$$

$$= \frac{10}{212} \Delta_{\alpha_\sigma}(u',v')$$
\[
\sum_{i=1}^{n} \alpha \int_{0}^{1} r \left[ |u_i(r) - v_i(r)| + |\overline{u_i}(r) - \overline{v_i}(r)| \right] dr = \Delta_{w,a}(u,v)
\]
i.e., conclusion (5) holds.

For any \( k > 0 \), we have
\[
\Delta_{w,a}(ku, kv) = \Delta_{w,a}(u,v)
\]
so conclusion (6) holds. Therefore, the proof of the theorem is completed.

Remark 4.2. (1) Although the conclusion (4) of Theorem 4.1 holds, \( u \leq v \leq w \) does not imply \( \Delta_{w,a}(u,v) \geq \Delta_{w,a}(u,v) \) (see Example 4.2). Comparing
\[
\Delta_{w,a}(u,v) = \sum_{i=1}^{n} \alpha \int_{0}^{1} r \left[ |u_i(r) - v_i(r)| + |\overline{u_i}(r) - \overline{v_i}(r)| \right] dr
\]
to
\[
\Delta_{w,a}(u,v) = \sum_{i=1}^{n} \alpha \int_{0}^{1} r \left[ |u_i(r) - v_i(r)| + |\overline{u_i}(r) - \overline{v_i}(r)| \right] dr
\]
we can see that the untruth of \( \Delta_{w,a}(u,v) \geq \Delta_{w,a}(u,v) \) is caused only by \( (M_a(u) + M_a(v))^\alpha \geq (M_a(u) + M_a(v))^\alpha \), and when \( (M_a(u) + M_a(v))^\alpha \) and \( (M_a(u) + M_a(v))^\alpha \) are properly smaller, \( u \leq v \leq w \) can imply \( \Delta_{w,a}(u,v) \geq \Delta_{w,a}(u,v) \). So, in general, we may choose \( a \) in (0,1) such that \( \Delta_{w,a} \) can reasonably characterize the degree of the difference of two fuzzy \( n \)-cell numbers.

(2) Generally speaking, the difference value \( \Delta_{a,a} \) does not satisfy the property of the triangular inequality, i.e., the inequality \( \Delta_{a,a}(u,v) \leq \Delta_{a,a}(u,w) + \Delta_{a,a}(w,v) \) does not necessarily hold for \( u,v,w \in L(E^*) \). Example 4.3 can show it.

Example 4.2. Let \( u,v,w \) be the 2-cell numbers defined by:
\[
u_i(x_i) = \begin{cases} 
1-x_i & \text{if } x_i \in [0,1] \\
1-x_i & \text{if } x_i \in [1,2] \\
0 & \text{if } x_i \in [1,3] 
\end{cases} \quad w_i(x_i) = \begin{cases} 
-1 + x_i & \text{if } x_i \in [1,2] \\
-2 + x_i & \text{if } x_i \in [2,3] \\
4 - x_i & \text{if } x_i \in [3,4] \\
0 & \text{if } x_i \in [3,4]
\end{cases}
\]
and \( i = 1,2 \). Then we know that \( u_i(r) = 0, u_i(r) = 0, v_i(r) = 1 + r, v_i(r) = 3 - r, w_i(r) = 2 + r, w_i(r) = 4 - r \) \( (r \in [0,1], i = 1,2) \), so we have \( u \leq v \leq w \), but we can see \( \Delta_{w,a}(u,w) \leq \Delta_{w,a}(u,v) \), from
\[
\Delta_{w,a}(u,w) = \alpha \int_{0}^{1} r \left[ |0 - 2 - r| + |0 - 4 + r| \right] dr + \alpha \int_{0}^{1} r \left[ |0 - 2 - r| + |0 - 4 + r| \right] dr = \frac{1}{3}
\]
and \( \Delta_{w,a}(u,v) = \alpha \int_{0}^{1} r \left[ |0 - 1 - r| + |0 - 3 + r| \right] dr + \alpha \int_{0}^{1} r \left[ |0 - 1 - r| + |0 - 3 + r| \right] dr = \frac{1}{2} \)

Example 4.3. Let \( u,v,w \) be the 2-cell numbers defined by:
\[
u_i(x_i) = \begin{cases} 
19 + x_i & \text{if } x_i \in [-9,10] \\
-10 - x_i & \text{if } x_i \in [-9,10] \\
0 & \text{if } x_i \notin [-9,10]
\end{cases} \quad w_i(x_i) = \begin{cases} 
19 + x_i & \text{if } x_i \in [-9,10] \\
10 - x_i & \text{if } x_i \in [-9,10] \\
0 & \text{if } x_i \notin [-9,10]
\end{cases}
\]
and \( i = 1,2 \). Then we know that \( u_i(r) = \frac{19}{10} + r, u_i(r) = \frac{1}{10} - r, v_i(r) = 1, v_i(r) = 1, w_i(r) = 2, w_i(r) = 2 \) \( (r \in [0,1], i = 1,2) \), so we have \( \Delta_{w,a}(u,v) = 19, \Delta_{w,a}(u,w) = \frac{29}{11} \) and \( \Delta_{w,a}(v,w) = \frac{1}{3} \), it implies \( \Delta_{w,a}(u,v) > \Delta_{w,a}(u,w) + \Delta_{w,a}(v,w) \).

Example 4.4. Let \( u,v,w \) be the 2-cell numbers (see Fig.1) defined by:
\[
u_i(x_i) = \begin{cases} 
x_i & \text{if } x_i \in [0,1] \\
2 & \text{if } x_i \in [1,2] \\
0 & \text{if } x_i \notin [0,1]
\end{cases} \quad w_i(x_i) = \begin{cases} 
1 - x_i & \text{if } x_i \in [1,2] \\
3 & \text{if } x_i \in [2,3] \\
0 & \text{if } x_i \notin [1,3]
\end{cases}
\]
and \( i = 1,2 \). Then we know that \( u_i(r) = r, u_i(r) = 2 - r, v_i(r) = 2, v_i(r) = 2, w_i(r) = 1 + r, w_i(r) = 3 - r \) \( (r \in [0,1], i = 1,2) \), so we can obtain that \( \Delta_{w,a}(u,v) = \frac{1}{2} = \Delta_{w,a}(u,w) + \Delta_{w,a}(v,w) \).

\[
\Delta_{w,a}(u,v) = \Delta_{w,a}(u,w) = \frac{2}{3} = \Delta_{w,a}(u,w) + \Delta_{w,a}(v,w)
\]
However, it is obvious (see Fig. 4.1) that the degree of the difference of \( u \) and \( v \) is different from the degree of the difference of \( u \) and \( w \).
In fact, sometimes, the degree of the difference of two fuzzy numbers is not only related with the metric and the sizes of them, but also related with the degree of fuzzy (we call it fuzzy degree) of them. Example 4.4 shows that for the two degrees of the differences indeed have some differences. In order to overcome the defects, we introduce the following two degrees of the difference value of two fuzzy numbers.

**Definition 4.2.** Let \( u, v \in L(E^n) \). We denote
\[
\Lambda_{\alpha}(u,v) = \left( \sum_{i=1}^{n} \alpha_i \int_0^1 (u_i(r) - v_i(r)) |r| dr \right) \cdot \exp \left( \sum_{i=1}^{n} \alpha_i \left( \int_0^1 u_i(t) dt - \int_0^1 v_i(t) dt \right) \right)
\]
and call \( \Lambda_{\alpha}(u,v) \) a difference value of \( u \) and \( v \) (with respect to the weight \( \alpha \) and parameter \( a \)), where,
\[
u_i^*(l) = \frac{u_i(l)+v_i(l)}{2}, \quad \nu_i^+(l) = \frac{u_i(l)-v_i(l)}{2}, \quad \text{and} \quad \alpha = (\alpha_1, \alpha_2, \ldots, \alpha_n)
\]
e \( R^n \) with \( \sum_{i=1}^{n} \alpha_i = 1 \) and \( \alpha_i \geq 0 \) \( (i=1,2,\ldots,n) \), and \( a \in (0, +\infty) \).

We denote \( \Lambda_{\alpha}(u,v) = \Lambda_{\alpha}(u,v) \) as
\[
\Lambda_{\alpha}(u,v) = \Lambda_{\alpha}(u,v)
\]
and \( \Lambda_{\alpha}(u,v) = \Lambda_{\alpha}(u,v) \) as \( u,v \in E \).

**Example 4.5.** Let \( u,v,w \) be the two \( 2 \) – cell numbers defined in Example 4.4. Then
\[
\Lambda_{\alpha}(u,v) = \left\{ \sum_{i=1}^{2} \alpha_i \int_0^1 \left( |r| + |2r-2| \right) dr \right\}
\]
\[
\cdot \exp \left( \sum_{i=1}^{2} \alpha_i \left( \int_0^1 u_i(t) dt - \int_0^1 v_i(t) dt \right) \right)
\]
\[
= \int_0^1 2 \cdot \exp(1)
\]
and
\[
\Lambda_{\alpha}(u,w) = \left\{ \sum_{i=1}^{2} \alpha_i \int_0^1 \left( |r-1| + |2r-2| \right) dr \right\}
\]
\[
\cdot \exp \left( \sum_{i=1}^{2} \alpha_i \left( \int_0^1 u_i(t) dt - \int_0^1 v_i(t) dt \right) \right)
\]
\[
= \int_0^1 2 \cdot \exp(1)
\]
so we see \( \Lambda_{\alpha}(u,v) > \Lambda_{\alpha}(u,w) \). Therefore, in this case, the difference value \( \Lambda_{\alpha} \) is more suitable than metrics and difference value \( \Lambda_{\alpha} \) to characterize the degree of the difference of two fuzzy \( n \) – cell numbers.

**Property 4.2.** Let \( u,v \in L(E^n) \), \( \alpha = (\alpha_1, \alpha_2, \ldots, \alpha_n) \in R^n \) with \( \sum_{i=1}^{n} \alpha_i = 1 \) and \( \alpha_i > 0 \) \( (i=1,2,\ldots,n) \), and \( a \in (0, +\infty) \).

Then
1. \( \Lambda_{\alpha}(u,v) \geq 0 \);
2. \( \Lambda_{\alpha}(u,v) = 0 \) if and only if \( u = v \);
3. \( \Lambda_{\alpha}(u,v) = \Lambda_{\alpha}(v,u) \);
4. \( \Lambda_{\alpha}(u+b,v+b) = \Lambda_{\alpha}(u,v) \) for any \( b \in R \);
5. \( \Lambda_{\alpha}(ku,kv) = k | \Lambda_{\alpha}(u,v) \) for any \( k \in R \).

**Proof.** It is obvious that the conclusions (1) and (3) hold. The proof of conclusion (2) can also be completed by imitating the proof of (3) of Theorem 3.2 by using Lemma 2.1 in [18].

For any \( b \in R \) and \( i=1,2,\ldots,n \), we have
\[
(u_i + b)(t) = \sup \{ r \in [0,1] : t \in [(u_i+b)(r),(u_i+b)(r)] \} = \sup \{ r \in [0,1] : t-b \in [u_i(r),u_i(r)] \} = u_i(t-b)
\]
hence
\[
\Lambda_{\alpha}(u+b,v+b) = \left\{ \sum_{i=1}^{n} \alpha_i \int_0^1 \left( |u_i(r) - v_i(r)| - |u_i(r) - v_i(r)| \right) dr \right\}
\]
\[
= \int_0^1 \sum_{i=1}^{n} \alpha_i \left( |u_i(r) - v_i(r)| - |u_i(r) - v_i(r)| \right) dr
\]
and call \( \Lambda_{\alpha}(u,v) \) a difference value of \( u \) and \( v \) (with respect to the weight \( \alpha \) and parameter \( a \)), where,
\[
\exp\left( a \sum_{\alpha_i} \alpha_i \left( \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (u(\alpha_i(t))+\Delta \alpha_i(t))dt - \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (v(\alpha_i(t))+\Delta \alpha_i(t))dt \right) \right) \\
+ \left| \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (u(\alpha_i(t))+\Delta \alpha_i(t))dt - \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (v(\alpha_i(t))+\Delta \alpha_i(t))dt \right| \\
= \left( \sum_{\alpha_i} \alpha_i \int_{0}^{1} r[i(\alpha_i(r))-\alpha_i(r)] + [\alpha_i(r)-\alpha_i(r)] \right) \\
\cdot \exp\left( a \sum_{\alpha_i} \alpha_i \left( \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (u(\alpha_i(t))+\Delta \alpha_i(t))dt - \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (v(\alpha_i(t))+\Delta \alpha_i(t))dt \right) \right) \\
+ \left| \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (u(\alpha_i(t))+\Delta \alpha_i(t))dt - \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (v(\alpha_i(t))+\Delta \alpha_i(t))dt \right| \\
= \left( k \sum_{\alpha_i} \alpha_i \int_{0}^{1} r[i(\alpha_i(r))-\alpha_i(r)] + [\alpha_i(r)-\alpha_i(r)] \right) \\
\cdot \exp\left( a \sum_{\alpha_i} \alpha_i \left( \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (u(\alpha_i(t))+\Delta \alpha_i(t))dt - \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (v(\alpha_i(t))+\Delta \alpha_i(t))dt \right) \right) \\
+ \left| \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (u(\alpha_i(t))+\Delta \alpha_i(t))dt - \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (v(\alpha_i(t))+\Delta \alpha_i(t))dt \right| \\
= \left| k \right| \left[ \Lambda_{a,v}(u,v) \right]
\]

For any \( k > 0 \), we have \( \Lambda_{a,v}(ku,kv) \)

\[
\exp\left( a \sum_{\alpha_i} \alpha_i \left( \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (u(\alpha_i(t))+\Delta \alpha_i(t))dt - \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (v(\alpha_i(t))+\Delta \alpha_i(t))dt \right) \right) \\
+ \left| \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (u(\alpha_i(t))+\Delta \alpha_i(t))dt - \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (v(\alpha_i(t))+\Delta \alpha_i(t))dt \right| \\
= \left| k \right| \left[ \Lambda_{a,v}(u,v) \right]
\]

If \( k = 0 \), it is obvious that \( \Lambda_{a,v}(ku,kv) = \left| k \right| \Lambda_{a,v}(u,v) \)

holds, so conclusion (5) holds. Therefore, the proof of the theorem is completed. \( \square \)

At the end of the section, combining the definitions of \( \Lambda_{a,v} \) and \( \Lambda_{a,v} \), we give the following definition of difference value \( \Gamma_{a,v} \).

**Definition 4.3.** Let \( u,v \in L(E^n) \) with \( M_a(u), M_v(v) \geq 0 \) and \( M_a(u) + M_v(v) \neq 0 \). We denote

\[
\Gamma_{a,v}(u,v) = \exp\left( a \sum_{\alpha_i} \alpha_i \left( \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (u(\alpha_i(t))+\Delta \alpha_i(t))dt - \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (v(\alpha_i(t))+\Delta \alpha_i(t))dt \right) \right) \\
+ \left| \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (u(\alpha_i(t))+\Delta \alpha_i(t))dt - \int_{\alpha_i(t)}^{\alpha_i(t)+\Delta t} (v(\alpha_i(t))+\Delta \alpha_i(t))dt \right| \\
= \left| k \right| \left[ \Lambda_{a,v}(u,v) \right]
\]

and call \( \Gamma_{a,v}(u,v) \) a difference value of \( u \) and \( v \) (with respect to \( \alpha \) and \( a = (a_i) \), where, \( \alpha = (\alpha_1,\alpha_2,\ldots,\alpha_n) \in R^n \) with \( \sum_{\alpha_i} \alpha_i = 1 \) and \( \alpha_i \geq 0 \). Then, \( \alpha = (a_1,a_2,\ldots,a_n) \in (0,\infty) \times (0,\infty) \).

We denote \( \Gamma_{a,v}(u,v) \) as \( \alpha = (1/n,1/n,\ldots,1/n) \), and \( \Gamma_{a,v}(u,v) = \Gamma_{a,v}(u,v) \) as \( u,v \in E \).

Likewise, we have the following properties about the difference value \( \Gamma_{a,v} \).

**Property 4.3.** Let \( u,v \in L(E^n) \) with \( M_a(u), M_v(v) \geq 0 \) and \( M_a(u) + M_v(v) \neq 0 \). Then

1. \( \Gamma_{a,v}(u,v) \geq 0 \)
2. \( \Gamma_{a,v}(u,v) = 0 \) if and only if \( u = v \)
3. \( \Gamma_{a,v}(u,v) = \Gamma_{a,v}(v,u) \)
(4) \( \Gamma_{a,b}(u + \hat{b}, v + \hat{b}) \leq \Gamma_{a,b}(u, v) \) for any \( b \in [0, +\infty) \);
(5) \( \Gamma_{a,b}(ku, kv) = k^{-2} \Gamma_{a,b}(u, v) \) for any \( k \in [0, +\infty) \), where \( b = (a_1, ka_2) \).

Proof. The proofs of the properties can be completed similarly with the proofs of Property 4.1 and 4.2, respectively, so we omit it.

V. PATTERN RECOGNITION BASED ON METRICS AND DIFFERENCE VALUES

In Section 3 and 4, we discussed metrics and difference values on \( L(E^n) \). In this section, we put forward an algorithmic version of pattern recognition in an imprecise or uncertain environment based on the metrics and difference values defined by us, and give examples to show the application (see Example 5.1) and rationality (see Example 5.2) of the method.

Consider a problem to identify an object (denoted by \( O \)) belonging to some one of \( l \) classes (denoted by \( C_1, C_2, \ldots, C_l \)) in an imprecise or uncertain environment. Let the objects have \( n \) characteristics. Since the problem discussed by us take on some imprecise or uncertain attributes, it is unsuitable (see Remark 2.1) that we use a crisp \( n \)–dimensional vector (i.e., a standard \( n \)–dimensional real number vector) to express the \( n \) character values of \( C_i \) (\( i = 1, 2, \ldots, l \)) or \( O \). Therefore, using the method of statistics, we construct \( l + 1 \) fuzzy \( n \)–cell numbers to express the \( n \) character values of \( C_1, C_2, \ldots, C_l \) and \( O \), respectively, and then put forward an algorithmic version of pattern recognition based on the metrics or the difference values defined by us.

Algorithmic version of pattern recognition based on metrics

The first step:

Depending on the practicality, we first find out one domain of the \( j \)th character value of \( C_i \) for each \( i \) (\( i = 1, 2, \ldots, l \)) and \( j \) (\( j = 1, 2, \ldots, n \)), and denote the said domain by \( D_j \).

We arbitrarily take \( m_i \) samples in \( C_i \) (\( i = 1, 2, \ldots, l \)), and gain \( m_i \) measure values (denoted by \( c_{i1}^i, c_{i2}^i, \ldots, c_{im_i}^i \) of the \( n \) characters of the \( m_i \) samples, denote \( c_i^j = (c_{i1}^j, c_{i2}^j, \ldots, c_{im_i}^j) \) \((m = 1, 2, \ldots, m_l)\), i.e., we gain the following tables:

\[
\begin{align*}
C_1: & \quad c_{11}^1, c_{12}^1, \ldots, c_{1n}^1, & c_{21}^1, c_{22}^1, \ldots, c_{2n}^1, & \ldots, & c_{m_1}^1, c_{m_2}^1, \ldots, c_{m_n}^1, \\
C_2: & \quad \vdots & \vdots & \vdots & \vdots \\
C_l: & \quad c_{11}^l, c_{12}^l, \ldots, c_{1n}^l, & c_{21}^l, c_{22}^l, \ldots, c_{2n}^l, & \ldots, & c_{m_1}^l, c_{m_2}^l, \ldots, c_{m_n}^l.
\end{align*}
\]

For \( C_i \) (\( i = 1, 2, \ldots, l \)), we directly work out the following means \( \mu_j^i = \frac{1}{m_i} \sum_{k=1}^{m_i} c_{ij}^i \) and standard deviations \( \sigma_j^i = \frac{1}{m_i - 1} \sum_{k=1}^{m_i} (c_{ij}^i - \mu_j^i)^2 \) (for \( j = 1, 2, \ldots, n \)) of the \( n \) character values of \( C_i \) (\( i = 1, 2, \ldots, l \)), respectively. We construct triangular model one-dimensional fuzzy numbers \( u_j^i \) (\( i = 1, 2, \ldots, l \), \( j = 1, 2, \ldots, n \)) as the following:

\[
u_j^i(x) = \begin{cases} 
\frac{x - (\mu_j^i - 2\sigma_j^i)}{2\sigma_j^i} & \text{if } x \in [\mu_j^i - 2\sigma_j^i, \mu_j^i] \cap D_j \\
\frac{(\mu_j^i + 2\sigma_j^i) - x}{2\sigma_j^i} & \text{if } x \in (\mu_j^i, \mu_j^i + 2\sigma_j^i] \cap D_j \\
0 & \text{if } x \notin [\mu_j^i - 2\sigma_j^i, \mu_j^i + 2\sigma_j^i] \cap D_j
\end{cases}
\]

or construct Gaussian model one-dimensional fuzzy numbers \( v_j^i \) (\( i = 1, 2, \ldots, l \), \( j = 1, 2, \ldots, n \)) as the following:

\[
v_j^i(x) = \begin{cases} 
\exp\left(-\frac{(x - \mu_j^i)^2}{2\sigma_j^i^2}\right) & \text{if } x \in D_j \\
0 & \text{if } x \notin D_j
\end{cases}
\]

We construct fuzzy \( n \)–cell numbers \( u^j = (u_{11}^j, u_{12}^j, \ldots, u_{m_l}^j) = (\min\{u_{1j}^1, u_{2j}^2, \ldots, u_{nj}^n\}) \) and \( v^j = (v_{11}^j, v_{12}^j, \ldots, v_{m_l}^j) = (\min\{v_{1j}^1, v_{2j}^2, \ldots, v_{nj}^n\}) \), \( i = 1, 2, \ldots, l \), use \( u^j \) or \( v^j \) to express the \( ith \) class \( C_i \) (\( i = 1, 2, \ldots, l \)).

The second step:

For the object \( O \) to be recognized, taking \( t \) samples in \( O \), we can again \( t \) classes of data about the \( n \) characters of \( O \) as the following:

\[
O: \quad o_{1t} \quad o_{2t} \quad \ldots \quad o_{nt}
\]

We work out the following means (denoted by \( \bar{o}_1, \bar{o}_2, \ldots, \bar{o}_n \)) and standard deviations (denoted by \( s_1, s_2, \ldots, s_n \)) of the \( n \) character values of \( O \):

\[
\bar{o}_i = \frac{1}{t} \sum_{i=1}^{t} o_{it} \quad (i = 1, 2, \ldots, n)
\]

and

\[
s_i = \sqrt{\frac{1}{t-1} \sum_{i=1}^{t} (o_{it} - \bar{o}_i)^2} \quad (i = 1, 2, \ldots, n)
\]

We construct triangular model one-dimensional fuzzy numbers \( w_j \) (\( i = 1, 2, \ldots, n \)) as the following:
or construct Gaussian model one-dimensional fuzzy numbers \( w'_i \) \((i = 1,2,...,n)\) as the following

\[
\begin{align*}
    y'_i(x) &= \exp\left(-\frac{(x - \bar{\alpha}_{i})^2}{2\sigma_i^2}\right) \quad \text{if} \quad x \in \bigcup_{j=1}^{n} D'_j \\
    &= 0 \quad \text{if} \quad x \not\in \bigcup_{j=1}^{n} D'_j 
\end{align*}
\]

We construct fuzzy \( n \)-cell numbers \( w = (w_1, w_2, ..., w_n) \) (\( w(x_1, x_2, ..., x_n) = \min[w_1(x_1), w_2(x_2), ..., w_n(x_n)] \)) and \( w' = (w'_1, w'_2, ..., w'_n) \) \((w'(x_1, x_2, ..., x_n) = \min[w'_1(x_1), w'_2(x_2), ..., w'_n(x_n)]\)), and use \( w \) or \( w' \) to express the object \( O \).

The third step:

Taking proper \( \alpha = (\alpha_1, \alpha_2, ..., \alpha_n) \) with \( \sum_{i=1}^{n} \alpha_i = 1 \) and \( \alpha_i \geq 0 \), \( i = 1,2,...,n \), and \( p \geq 1 \), we compute the metrics

\[
D_{\alpha,p}(w, u^i) = \frac{1}{2} \left[ \left\{ \sum_{i=1}^{n} \left| \left( \frac{1}{2} \sum_{j=1}^{p} \alpha_j \cdot \left( |w(r) - u_j(r)| + |w(r) - u'_j(r)| \right) \right)^p \right. \right. \\
\left. \left. \right. \right] \right] 
\]

or

\[
D_{\alpha,p}(w', v^i) = \frac{1}{2} \left[ \left\{ \sum_{i=1}^{n} \left| \left( \frac{1}{2} \sum_{j=1}^{p} \alpha_j \cdot \left( |w'(r) - v_j(r)| + |w'(r) - v'_j(r)| \right) \right)^p \right. \right. \\
\left. \left. \right. \right] \right] 
\]

The fourth step:

We choose \( u^i \) in \( u^i, u^j, ..., u^l \), or \( v^i \) in \( v^i, v^j, ..., v^l \) such that

\[
\begin{align*}
    &D_{\alpha,p}(w, u^i) = \min \{D_{\alpha,p}(w, u^1), D_{\alpha,p}(w, u^2), ..., D_{\alpha,p}(w, u^l)\} \\
    \text{or} \quad &D_{\alpha,p}(w', v^i) = \min \{D_{\alpha,p}(w', v^1), D_{\alpha,p}(w', v^2), ..., D_{\alpha,p}(w', v^l)\}
\end{align*}
\]

Then we can consider that object \( O \) belongs to the \( j_0 \)-th class \( C_{j_0} \), or belongs to the \( j_0 \)-th class \( C_{j_0} \).

Remark 5.1. In the third and fourth steps of the above method, we can have the metric \( \bar{D}_{\alpha,p} \) replace the metric \( D_{\alpha,p} \), as a result of which, we can also set up a method based on the metric \( \bar{D}_{\alpha,p} \).

Algorithmic version of pattern recognition based on difference values

The first step and the second step:

They are respectively same with the first step and the second step of the method of pattern recognition based on the metric, as above.

The third step:

Taking proper \( \alpha = (\alpha_1, \alpha_2, ..., \alpha_n) \) with \( \sum_{i=1}^{n} \alpha_i = 1 \) and \( \alpha_i \geq 0 \), \( i = 1,2,...,n \), and \( a = (a_1, a_2) \in (0, +\infty) \times (0, +\infty) \), we compute the difference values

\[
\begin{align*}
    &\Gamma_{\alpha,p}(w, u^i) = \frac{1}{2} \left[ \left\{ \sum_{i=1}^{n} \left| \left( \frac{1}{2} \sum_{j=1}^{p} \alpha_j \cdot \left( \frac{1}{2} \sum_{j=1}^{p} \alpha_j \cdot \left( |w(r) - u_j(r)| + |w(r) - u'_j(r)| \right) \right)^p \right. \right. \\
    \text{or} \quad &\Gamma_{\alpha,p}(w', v^i) = \frac{1}{2} \left[ \left\{ \sum_{i=1}^{n} \left| \left( \frac{1}{2} \sum_{j=1}^{p} \alpha_j \cdot \left( \frac{1}{2} \sum_{j=1}^{p} \alpha_j \cdot \left( |w'(r) - v_j(r)| + |w'(r) - v'_j(r)| \right) \right)^p \right. \right. \\
\end{align*}
\]

The fourth step:

We choose \( u^i \) in \( u^1, u^2, ..., u^l \), or \( v^i \) in \( v^1, v^2, ..., v^l \) such that

\[
\begin{align*}
    &\Gamma_{\alpha,p}(w, u^i) = \min \{\Gamma_{\alpha,p}(w, u^1), \Gamma_{\alpha,p}(w, u^2), ..., \Gamma_{\alpha,p}(w, u^l)\} \\
    \text{or} \quad &\Gamma_{\alpha,p}(w', v^i) = \min \{\Gamma_{\alpha,p}(w', v^1), \Gamma_{\alpha,p}(w', v^2), ..., \Gamma_{\alpha,p}(w', v^l)\}
\end{align*}
\]

Then we can consider that object \( O \) belongs to the \( j_0 \)-th class \( C_{j_0} \), or belongs to the \( j_0 \)-th class \( C_{j_0} \).

Remark 5.2. In the third and fourth steps of the method above, we can have the difference value \( \Delta_{\alpha,a} \) or \( \Lambda_{\alpha,a} \) replace the difference value \( \Gamma_{\alpha,a} \), as a result of which, we can also set up a method based on the difference value \( \Delta_{\alpha,a} \) or \( \Lambda_{\alpha,a} \).

In order to be more obvious, we may use the following diagram to illustrate the methods set up by us.
Example 5.1. Suppose that some terrain consists of five different types of land based cover: \( C_1 \): Road; \( C_2 \): Farm or Crop; \( C_3 \): Korean Pine accounts for the main part; \( C_4 \): Boreal and Broad-leaf Mixture Forest; \( C_5 \): Birch Forest. For the five types of land cover (\( C_1, C_2, C_3, C_4, C_5 \)) and by using the four wave bands: MSS-4, MSS-5, MSS-6, MSS-7, we take 10 samples, and acquire the following data:

<table>
<thead>
<tr>
<th>( C_1 )</th>
<th>Sample 1</th>
<th>18.62</th>
<th>20.71</th>
<th>58.20</th>
<th>26.72</th>
<th>Sample 4</th>
<th>18.76</th>
<th>15.95</th>
<th>56.35</th>
<th>22.89</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sample 2</td>
<td>19.76</td>
<td>17.01</td>
<td>51.02</td>
<td>24.32</td>
<td>Sample 3</td>
<td>18.24</td>
<td>19.46</td>
<td>48.12</td>
<td>26.33</td>
<td>Sample 5</td>
</tr>
<tr>
<td>Sample 6</td>
<td>19.90</td>
<td>20.13</td>
<td>50.82</td>
<td>25.05</td>
<td>Sample 7</td>
<td>19.16</td>
<td>18.58</td>
<td>52.30</td>
<td>22.21</td>
<td>Sample 8</td>
</tr>
<tr>
<td>Sample 9</td>
<td>19.36</td>
<td>17.98</td>
<td>48.26</td>
<td>23.86</td>
<td>Sample 10</td>
<td>18.48</td>
<td>16.46</td>
<td>46.63</td>
<td>27.46</td>
<td></td>
</tr>
</tbody>
</table>

\( C_2 \) Sample 1 | 21.36 | 32.28 | 53.61 | 24.95 | Sample 4 | 20.26 | 21.56 | 41.37 | 24.39 | Sample 10 | 25.42 | 30.52 | 50.46 | 22.59 |

\( C_3 \) Sample 1 | 15.01 | 13.30 | 40.50 | 19.37 | Sample 2 | 15.60 | 12.56 | 38.81 | 16.35 | Sample 3 | 15.82 | 12.79 | 37.70 | 18.16 |

\( C_4 \) Sample 1 | 16.10 | 13.80 | 42.10 | 20.75 | Sample 4 | 13.80 | 11.94 | 32.10 | 15.54 | Sample 7 | 15.90 | 10.98 | 30.87 | 14.29 |

\( C_5 \) Sample 1 | 16.82 | 13.67 | 37.64 | 18.62 | Sample 8 | 16.82 | 13.67 | 37.64 | 18.62 |

Taking \( D_j = (0, +\infty) \) (\( i = 1,2,3,4 \) and \( j = 1,2,3,4,5 \) ) then according to

\[
u_j(x) = \begin{cases} 
\frac{x - (\mu_j - 2\sigma_j)}{2\sigma_j} & \text{if } x \in [\mu_j - 2\sigma_j, \mu_j] \cap D_j^i \\
\frac{(\mu_j + 2\sigma_j) - x}{2\sigma_j} & \text{if } x \in (\mu_j, \mu_j + 2\sigma_j] \cap D_j^i \\
0 & \text{if } x \not\in [\mu_j - 2\sigma_j, \mu_j + 2\sigma_j] \cap D_j^i 
\end{cases} \]

we have

\[
u_j(x) = \begin{cases} \frac{x - 17.96}{1.10} & \text{if } x \in [17.96, 19.06] \\
\frac{x - 15.08}{3.16} & \text{if } x \in [15.08, 18.24] \\
0 & \text{if } x \not\in [15.08, 18.24] 
\end{cases} \]

\[
u_j(x) = \begin{cases} \frac{x - 24.64}{8.56} & \text{if } x \in [24.64, 51.20] \\
\frac{x - 21.28}{3.96} & \text{if } x \in [21.28, 25.24] \\
0 & \text{if } x \not\in [21.28, 25.24] 
\end{cases} \]
So we can obtain the fuzzy data: positions, or using various viewers, and obtain the following means and standard deviations:

Using the same four wave bands: MSS-4, MSS-5, MSS-6, MSS-7, we now proceed to examine some zone (i.e., object, denoted by $O$) 12 times, stochastically, at various times or positions, or using various viewers, and obtain the following data:

and for $r \in [0,1]$

We can work out the following means and standard deviations: $\bar{O} = 17.09$, $s_1 = 0.77$, $\bar{O}_1 = 13.17$, $s_2 = 0.50$

So we can obtain the fuzzy 4-cell number $o = (o_1, o_2, o_3, o_4)$, i.e.,

that can be used to represent $O$, where,

$$o(x_1, x_2, x_3, x_4) = \frac{-x - 15.55}{1.54} \quad \text{if} \ x \in [15.55, 17.09]$$

$$o(x_1, x_2, x_3, x_4) = \frac{-x + 12.17}{1.00} \quad \text{if} \ x \in [12.17, 13.17]$$

$$o(x_1, x_2, x_3, x_4) = \frac{-x - 43.22}{1.98} \quad \text{if} \ x \in [43.02, 45.00]$$
and for \( r \in [0,1] \).

\[
\alpha_a(r) = \begin{cases} 
1 - 2.02, & x \in [43.08, 45.10] \\
\frac{47.12 - x}{2}, & x \in [45.10, 47.12] \\
0, & x \notin [43.08, 47.12]
\end{cases}
\]

Taking \( \alpha = \left( \frac{1}{4}, \frac{1}{4}, \frac{1}{4}, \frac{1}{4} \right) \) and \( a = \left( \frac{1}{5}, \frac{1}{5} \right) \), By

\[
\Gamma_{u',v'}(u,v) = \exp \left( a \sum_{i=1}^{n} \int_{a_{i}}^{b} \left( u(r) + v(r) - u'(r) - v'(r) \right) dr \right)
\]

we can obtain \( \Gamma_{u',v'}(u,v) = 3.36 \), \( \Gamma_{u',u'}(u,v) = 10.34 \), \( \Gamma_{u',u'}(u,v) = 4.27 \), \( \Gamma_{u',u'}(u,v) = 1.11 \), \( \Gamma_{u',u'}(u,v) = 0.03 \). From \( \Gamma_{u',v'}(u,v) = \min(\Gamma_{u',u'}, \Gamma_{u',u'}, \Gamma_{u',u'}, \Gamma_{u',u'} \) \), we know that \( O \) belongs to \( C \), i.e., the zone measured by us is covered by Birch Forest.

Remark 5.3. Although, only for the example, using mean vectors \( (\mu_1', \mu_2', \mu_3', \mu_4') \) and \( (\bar{\sigma}_1', \bar{\sigma}_2', \bar{\sigma}_3', \bar{\sigma}_4') \) to represent respectively \( C_1, C_2, C_3, C_4 \) and \( O \), we perhaps also judge that \( O \) belongs to \( C \) by the usual Euclidean metrics, we still emphasize that using fuzzy \( n \)-cell numbers to deal with imprecise or uncertain quantities is better than using crisp \( n \)-dimensional vectors. The following example (to simplify and shorten the problem, we only consider 1-dimensional case) will show this.

Example 5.2. The following two classes of ferrous quantities (kilogram per hundred kilogram) of minerals come respectively two different mine areas (denoted by \( A \) and \( B \)).

\[
\begin{align*}
A: & 10.20, 11.76, 8.31, 9.02, 9.63, 8.33, 11.36, 12.30, 12.03, 7.98 \\
B: & 52.33, 79.34, 34.51, 62.34, 82.26, 28.36, 17.37, 25.32, 10.11, 8.34
\end{align*}
\]

Suppose that one group (denoted by \( C \)) of minerals comes from the one of \( A \) and \( B \). The problem to be solved is to identify if \( C \) comes from \( A \) or \( B \). We take samples, and acquire the following data for \( C \):

\[
\begin{align*}
\end{align*}
\]

We can work out: \( \mu_1 = 10.09 \), \( \sigma_1 = 1.67 \), \( \mu_2 = 40.03 \), \( \sigma_2 = 27.43 \), \( \mu_3 = 24.52 \) and \( \sigma_3 = 18.86 \).

If we use crisp means to represent \( A \), \( B \), and \( C \), then we have \( A = 10.09 \), \( B = 40.03 \), \( C = 24.52 \) and \( d(C,A) = 14.43 < 15.51 = d(C,B) \). If we regard \( d(C,A) < d(C,B) \) as evidence, we can draw a conclusion that \( C \) comes from \( A \). However, the conclusion does not accord with fact. We should note that although \( d(C,A) < d(C,B) \), the difference of \( d(C,A) \) and \( d(C,B) \) is small. Furthermore, from the statistical data, we can see that the ferrous quantities of minerals coming from \( A \) are more coincident, but \( B \) and \( C \) are not. It is almost impossible that some minerals in \( C \) come from \( A \), such as, minerals with ferrous quantities 76.02 and 28.56. So we may judge that \( C \) comes from \( B \).

If we use fuzzy 1-cell numbers to represent \( A \), \( B \), and \( C \), then we have

\[
\begin{align*}
A(x) = & \begin{cases} 
\frac{x - 6.75}{3.34}, & x \in [6.75, 10.09] \\
\frac{2.21 - x}{3.34}, & x \in [10.09, 10.34] \\
0, & x \notin [6.75, 10.34]
\end{cases}
\]

\[
B(x) = \begin{cases} 
\frac{x + 14.83}{54.86}, & x \in [0, 40.03] \\
\frac{94.89 - x}{94.89}, & x \in [40.03, 94.89] \\
0, & x \notin [0, 94.89]
\end{cases}
\]

\[
C(x) = \begin{cases} 
\frac{x + 13.20}{37.72}, & x \in [0, 24.52] \\
\frac{62.24 - x}{37.72}, & x \in [24.52, 62.24] \\
0, & x \notin [0, 62.24]
\end{cases}
\]

Taking \( x = 3.34 \), \( y = 6.75 \), \( z = 4.27 \), we have

\[
A(x) = \begin{cases} 
54.86, & r \in [0, 0.27] \\
0, & r \notin [0, 0.27]
\end{cases}
\]

\[
B(x) = \begin{cases} 
94.89, & r \in [0, 0.35] \\
37.72 - r, & r \notin [0, 0.35]
\end{cases}
\]

\[
C(x) = \begin{cases} 
106.69, & r \in [0, 1] \\
21.77, & r \notin [0, 1]
\end{cases}
\]

Thus we can affirm that \( C \) comes from \( B \).

VI. Conclusion

In this paper, we suggest using fuzzy \( n \)-cell numbers to represent imprecise or uncertain multichannel digital signals, and put forward a method (see the first or second step of the algorithmic version in Section 5, or see Example 2.1) of constructing such fuzzy \( n \)-cell numbers. Although the metrics \( D \) and \( D_e \) have been studied formerly in [14, 15], in view of the roughness of \( D \) and \( D_e \), we define two new metrics on fuzzy \( n \)-cell number space in order that they can better characterize the degree of the difference of two objects in some imprecise or uncertain environment, and we study their properties (Section 3). In some applications, metrics are unsuitable for use in finding the difference of two fuzzy \( n \)-cell numbers, so we introduce the concepts of difference values \( A_{u,v}, A_{u,u} \), and \( A_{u,v} \) study their properties, and show the rationality for their use in characterizing the degree of the difference of two fuzzy \( n \)-cell numbers by Remarks and examples (see Section 4). Finally, in Section 5, we put forward an algorithmic version of pattern recognition in an imprecise or uncertain environment based on the metrics and difference values defined by us, and give examples to show the application (see Example 5.1) and rationality (see Example 5.2) of the methods.
ACKNOWLEDGEMENT

The authors would like to thank the Associate Editor and reviewers for their valuable suggestions and comments which have greatly improved the presentation of the paper. This work is partially supported by the Engineering and Physical Sciences Research Council, UK (EP/F029195).
