Some Refinements of Ky Fan's Inequality

SOME REFINEMENTS OF KY FAN'S INEQUALITY

PENG GAO

Abstract. We give some refinements of Ky Fan's inequality and also prove some inequalities involving the symmetric means.

1. Introduction

Let $M_{n,r}(\mathbf{x})$ be the generalized weighted power means: $M_{n,r}(\mathbf{x}) = (\sum_{i=1}^{n} \omega_i x_i^r)^{\frac{1}{r}}$, where $\omega_i > 0, 1 \leq i \leq n$ with $\sum_{i=1}^{n} \omega_i = 1$ and $\mathbf{x} = (x_1, x_2, \cdots, x_n)$. Here $M_{n,0}(\mathbf{x})$ denotes the limit of $M_{n,r}(\mathbf{x})$ as $r \to 0^+$. Unless specified, we always assume $0 < x_1 \leq x_2 \cdots \leq x_n$. We denote $\sigma_n = \sum_{i=1}^{n} \omega_i (x_i - A_n)^2$.

To any given $\mathbf{x}, t \geq 0$ we associate $\mathbf{x}' = (1 - x_1, 1 - x_2, \cdots, 1 - x_n), \mathbf{x}_t = (x_1 + t, \cdots, x_n + t)$. When there is no risk of confusion, we shall write $M_{n,r}$ for $M_{n,r}(\mathbf{x})$, $M_{n,r,t}$ for $M_{n,r}(\mathbf{x}_t)$ and $M'_{n,r}$ for $M_{n,r}(\mathbf{x}')$ if $x_n < 1$. The meaning of $P_s, P'_s, P_{s,t}$ are similar. We also define $A_n = M_{n,1}, G_n = M_{n,0}, H_n = M_{n,-1}$ and similarly for $A'_n, G'_n, H'_n, A_{n,t}, G_{n,t}, H_{n,t}$.

Recently, the author[7] proved the following result.

Theorem 1.1. *For $r > s, x_1 > 0$, the following inequalities are equivalent:*

$$\frac{r-s}{2x_1}\sigma_n \geq \quad M_{n,r} - M_{n,s} \quad \geq \frac{r-s}{2x_n}\sigma_n, \tag{1.1}$$

$$\frac{x_n}{1-x_n}(M_{n,r} - M_{n,s}) \geq \quad M'_{n,r} - M'_{n,s} \quad \geq \frac{x_1}{1-x_1}(M_{n,r} - M_{n,s}), \tag{1.2}$$

where in (1.2) *we require $x_n < 1$.*

For extensions and refinements of (1.1), see [2], [9],[12] and [13]. Inequality (1.2) is commonly referred as the additive Ky Fan's inequality. We refer the reader to the survey article[1] and the references therein for an account of Ky Fan's inequality.

D.Cartwright and M.Field[4] first proved the validity of (1.1) for $r = 1, s = 0$. Under the assumption $x_n \leq 1/2$, it is easy to show(see [6]) if $\beta \leq \alpha$, then $A_n^\alpha - G_n^\alpha \geq A_n^{'\alpha} - G_n^{'\alpha}$ implies $A_n^\beta - G_n^\beta \geq A_n^{'\beta} - G_n^{'\beta}$ and $A_n^\beta - G_n^\beta \leq A_n^{'\beta} - G_n^{'\beta}$ implies $A_n^\alpha - G_n^\alpha \leq A_n^{'\alpha} - G_n^{'\alpha}$. Thus if $x_n \leq 1/2$, the above Theorem then implies $A_n^\alpha - G_n^\alpha \geq A_n^{'\alpha} - G_n^{'\alpha}$ for $\alpha \leq 1$. Alzer[3] has given a counter example to show that $A_n^\alpha - G_n^\alpha$ and $A_n^{'\alpha} - G_n^{'\alpha}$ are not comparable in general for any fixed $\alpha > 1$. It is then interesting to seek for certain $\alpha > 1$, as a function of the weights so that $A_n^\alpha - G_n^\alpha$ and $A_n^{'\alpha} - G_n^{'\alpha}$ are comparable. One motivation is the following result of Pečarić and Alzer[15](see also [1], Theorem 7.2).

Theorem 1.2. *For $\omega_i = 1/n, 0 < x_1 \leq x_2 \leq \cdots \leq x_n \leq 1/2$,*

$$A_n^n - G_n^n \leq A_n^{'n} - G_n^{'n}. \tag{1.3}$$

Theorem 1.2 suggests that $A_n^\alpha - G_n^\alpha \leq A_n^{'\alpha} - G_n^{'\alpha}$ for $\alpha = 1/q$ with $q = \min\{\omega_i\}$. We will show this is indeed the case in section 3. A similar result is also proved there. The idea of the proof of (1.3) also allows us to establish some inequalities involving the symmetric means in section 4.

2. Lemmas

Lemma 2.1. *For $0 < q < 1$, $0 < G_n \leq A_n \leq 1$, $f(q) = 2q(A_n^{\frac{1}{q}} - G_n^{\frac{1}{q}})$ is an increasing function of q.*

Proof. Let $x = A_n, y = G_n$, then $f'(q) = 2(x^{\frac{1}{q}} - y^{\frac{1}{q}}) - 2(\ln(x^{\frac{1}{q}})x^{\frac{1}{q}} - \ln(y^{\frac{1}{q}})y^{\frac{1}{q}}) \geq 0$, since $u - u\ln u$ increases with respect to u for $0 < u \leq 1$. □

Lemma 2.2. *For $0 < q \leq 1$, $(1-q)^{1/q-1}$ is an increasing function of q, in particular, $(1-q)^{1/q-1} \leq 1/2$ when $0 < q \leq 1/2$ and the above inequality reverses when $1/2 \leq q < 1$. In either case, equality holds if and only if $q = 1/2$.*

Proof. It suffices to show $f'(q) \geq 0$ for $0 < q < 1$ with $f(q) = (1/q - 1)\ln(1-q)$. Now $f'(q) = -h(q)/q^2$ with $h(q) = q + \ln(1-q) < 0$ for $0 < q < 1$, we are done. □

3. The Main Results

To motivate our next result, we note that L. Hoehn and I. Niven[10] showed $A_{n,t} - G_{n,t}$ is a decreasing function of t. It then follows that $f(t, \alpha) = A_{n,t}^{\alpha} - G_{n,t}^{\alpha}$ is decreasing as a function of t(See [8], Theorem 2.1) for $\alpha \leq 1$. It's natural to ask whether one can have similar results for $\alpha \geq 1$ and we have the following

Proposition 3.1. *For $0 < x_1 \leq \cdots \leq x_n$, $q = \min\{\omega_i\}, t \geq 0$, $f(t, \alpha)$ is a decreasing function of t for $\alpha \leq (1-q)^{-1}$ and $f(t, \alpha)$ is an increasing function for $\alpha \geq q^{-1}$.*

Proof. We will show the first assertion and the proof for the other one is similar. By Theorem 2.1 in [8], it suffices to prove the above result for $\alpha = (1-q)^{-1}$. Let $f(t) = A_{n,t}^{(1-q)^{-1}} - G_{n,t}^{(1-q)^{-1}}$, it suffices to show $f'(0) \leq 0$ which is equivalent to $A_n^q H_n^{1-q} \leq G_n$, which is the weighted Sierpiński's inequality(See [7] for an extension of this) and this completes the proof. □

Theorem 3.1. *For $0 < q \leq \min\{\omega_i\}$,*

$$x_1^{\frac{1}{1-q}-2}\sigma_n \geq 2(1-q)(A_n^{\frac{1}{1-q}} - G_n^{\frac{1}{1-q}}) \geq x_n^{\frac{1}{1-q}-2}\sigma_n \tag{3.1}$$

with equality holding if and only if $n = 2, q = 1/2$ or $x_1 = x_2 = \cdots = x_n$.

Proof. We prove the right-hand side inequality of (3.1) first. By homogeneity, we may assume $0 \leq x_1 < x_2 < \cdots < x_n = 1$ in (3.1) and define

$$D_n(x_1, \cdots, x_{n-1}) = A_n^{\frac{1}{1-q}} - G_n^{\frac{1}{1-q}} - \sigma_n/2(1-q). \tag{3.2}$$

We want to show $D_n \geq 0$. Let $\mathbf{a} = (a_1, \cdots, a_{n-1}) \in [0,1]^{n-1}$ be the point in which the absolute minimum of D_n is reached.

We may assume $a_1 \leq a_2 \leq \cdots \leq a_{n-1}$ and let $a_n = 1$. If $a_i = a_{i+1}$ for some $1 \leq i \leq n-1$, by combining a_i with a_{i+1} and ω_i with ω_{i+1}, while noticing increasing q will decrease the value of $(1-q)(A_n^{\frac{1}{1-q}} - G_n^{\frac{1}{1-q}})$ by Lemma 2.1, we can reduce the determination of the absolute minimum of D_n to that of D_{n-1} with different weights. Thus without loss of generality, we may assume $a_1 < a_2 < \cdots < a_{n-1} < 1$. If $a_1 > 0$ then $\mathbf{a}$ is an interior point of $[0,1]^{n-1}$, then we obtain

$$\nabla D_n(a_1, \cdots, a_{n-1}) = 0$$

such that $a_1, \cdots, a_{n-1}$ solve the equation

$$x^2 - (A_n + A_n^{\frac{q}{1-q}})x + G_n^{\frac{1}{1-q}} = 0. \tag{3.3}$$

The above equation has at most two roots(regarding A_n, G_n as constants), so we are reduced to the case $n = 3$. But if $a_1 < a_2 < 1$ both satisfy (3.3), we will have

$$a_1 a_2 = a_1^{\omega_1/(1-q)} a_2^{\omega_2/(1-q)},$$

which is impossible since $\omega_1+q\leq 1, \omega_2+q\leq 1$ and the two equalities can's hold at the same time. Thus if $a_1>0$, we only need to prove $D_2\geq 0$. In this case, by letting $x=a_1>0$, we get

$$D_2(x)=(\omega_1 x+\omega_2)^{\frac{1}{1-q}}-x^{\frac{\omega_1}{1-q}}-\frac{\omega_1\omega_2(x-1)^2}{2(1-q)}.$$

It's easy to check $D_2(1)=D_2'(1)=0$ and

$$\begin{aligned}\frac{1-q}{\omega_1}D''(x) &= \frac{q\omega_1}{1-q}(\omega_1 x+\omega_2)^{\frac{2q-1}{1-q}}-(\frac{\omega_1}{1-q}-1)x^{\frac{\omega_1}{1-q}-2}-\omega_2\\ &\geq \frac{q\omega_1}{1-q}+1-\frac{\omega_1}{1-q}-\omega_2=0.\end{aligned}$$

with equality holding if and only if $x=1$ or $q=1/2$. Hence by the Taylor expansion at 1, $D_2(x)\geq 0$ with equality holding if and only if $x=1$ or $q=1/2$.

If $\mathbf{a}$ is a boundary point of $[0,1]^{n-1}$, then $a_1=0$, (3.2) is reduced to

$$E_n(x_1=0,\cdots,x_{n-1})=A_n^{\frac{1}{1-q}}-\sigma_n/2(1-q).$$

We now show $E_n\geq 0$. Let $(a_2,\cdots,a_{n-1})\in[0,1]^{n-2}$ be the point in which the absolute minimum of E_n is reached. Similar to the argument above, we may assume $0=a_1<a_2<\cdots<a_{n-1}<1$ and it's easy to show by using the method above that we only need to consider the cases $n=2$ and $n=3$. $E_2\geq 0$ is equivalent to $q^{1/(1-q)}\geq q/2$ and $g(q)=(1-q)^{1/(1-q)}-q/2\geq 0$. The first inequality follows from Lemma 2.2 and one checks $g(q)$ is a decreasing function of q hence $g(q)\geq g(1/2)=0$. For the case $n=3$, we set $x=a_2$ so that

$$\frac{1-q}{\omega_2}E_3'(a_2)=A_3^{\frac{q}{1-q}}-(a_2-A_3)=0.$$

Using this we get

$$\begin{aligned}\frac{(1-q)^2A_3}{\omega_2}E_3''(a_2) &= q\omega_2A_3^{\frac{q}{1-q}}-(1-q)(1-\omega_2)A_3\\ &= q\omega_2(a_2-A_3)-(1-q)(1-\omega_2)A_3\\ &= q\omega_2((1-\omega_2)a_2-\omega_3)-(1-q)(1-\omega_2)(\omega_2a_2+\omega_3)\\ &= \omega_2(1-\omega_2)(2q-1)a_2-q\omega_2\omega_3-(1-q)(1-\omega_2)\omega_3<0.\end{aligned}$$

This implies $E_3(x)$ takes its local maximum at a_2 so in order to show $E_3\geq 0$, we only need to show it for the cases $a_2=0$ or $a_2=1$ and we are then back to the case $n=2$ and this completes the proof for the right-hand side inequality of (3.1).

For the left-hand side inequality of (3.1), we may again assume $0\leq x_1<x_2<\cdots<x_n=1$ and define

$$F_n(x_1,\cdots,x_{n-1})=\sigma_n/2(1-q)-x_1^{2-\frac{1}{1-q}}(A_n^{\frac{1}{1-q}}-G_n^{\frac{1}{1-q}}). \tag{3.4}$$

We want to show $F_n\geq 0$. Let $\mathbf{a}=(a_1,\cdots,a_{n-1})\in[0,1]^{n-1}$ be the point in which the absolute minimum of F_n is reached.

Again we may assume $a_1<a_2<\cdots<a_{n-1}<1$. If $a_1>0$ then $\mathbf{a}$ is an interior point of $[0,1]^{n-1}$, and we obtain

$$\nabla F_n(a_1,\cdots,a_{n-1})=0$$

such that $a_2,\cdots,a_{n-1}$ solve the equation $f(x)=0$ where

$$f(x)=x^2-(A_n+a_1^{2-\frac{1}{1-q}}A_n^{\frac{q}{1-q}})x+a_1^{2-\frac{1}{1-q}}G_n^{\frac{1}{1-q}}.$$

The above equation has at most two roots(regarding a_1, A_n, G_n as constants), so we are reduced to the case $n=4$. But note we also have $f(a_1)=\omega_1^{-1}(2-\frac{1}{1-q})a_1^{2-\frac{1}{1-q}}(A_n^{\frac{1}{1-q}}-G_n^{\frac{1}{1-q}})\geq 0$ and $f(1)\leq 0$ since otherwise by decreasing $a_n=1$, we will get a smaller value of F_n, contradicts to our assumption. Thus we only need to consider the case $n = 3$. In this case a_2 is a root of $f(x) = 0$ and the other root b satisfies $b \geq 1$ since $\lim_{x\to\infty} f(x) = \infty$. But then we will have

$$a_2 \leq ba_2 = a_1^{2-\frac{1}{1-q}} a_1^{\omega_1/(1-q)} a_2^{\omega_2/(1-q)},$$

which implies

$$a_1^{1-\omega_2/(1-q)} \leq a_2^{1-\omega_2/(1-q)} \leq a_1^{2-\frac{1}{1-q}} a_1^{\omega_1/(1-q)},$$

which is impossible. Thus if $a_1 > 0$, we only need to prove $F_2 \geq 0$ and this case can be proved similarly to our treatment of $D_2 \geq 0$.

If $\mathbf{a}$ is a boundary point of $[0,1]^{n-1}$, then $a_1 = 0$, (3.4) follows trivially and this completes the proof for the left-hand side inequality of (3.1). □

Corollary 3.1. *For* $0 < q \leq \min\{\omega_i\}, 0 < x_1 \leq x_2 \leq \cdots \leq x_n < 1, x_1 \neq x_n$,

$$(\frac{1-x_1}{x_1})^{2-\frac{1}{1-q}} \geq \frac{A_n^{\frac{1}{1-q}} - G_n^{\frac{1}{1-q}}}{A_n^{'\frac{1}{1-q}} - G_n^{'\frac{1}{1-q}}} \geq (\frac{1-x_n}{x_n})^{2-\frac{1}{1-q}}.$$

Proof. Apply (3.1) to both $\mathbf{x}$, $\mathbf{x}'$ and take their quotients gives the desired result. □

Theorem 3.2. *For* $0 < q \leq \min\{\omega_i\}$,

$$x_n^{\frac{1}{q}-2}\sigma_n \geq 2q(A_n^{\frac{1}{q}} - G_n^{\frac{1}{q}}) \geq x_1^{\frac{1}{q}-2}\sigma_n \tag{3.5}$$

with equality holding if and only if $n = 2, q = 1/2$ *or* $x_1 = x_2 = \cdots = x_n$.

Proof. We prove the left-hand side inequality first. By homogeneity, we may assume $0 \leq x_1 < x_2 < \cdots < x_n = 1$ in (3.5) and define

$$D_n(x_1, \cdots, x_{n-1}) = \frac{1}{2q}\sigma_n - (A_n^{\frac{1}{q}} - G_n^{\frac{1}{q}}).$$

We want to show $D_n \geq 0$. Let $\mathbf{a} = (a_1, \cdots, a_{n-1}) \in [0,1]^{n-1}$ be the point in which the absolute minimum of D_n is reached. As in the proof of Theorem 3.1 and again use Lemma 2.1, we may assume $a_1 < a_2 < \cdots < a_{n-1} < a_n = 1$. If $a_1 > 0$ then $\mathbf{a}$ is an interior point of $[0,1]^{n-1}$, then we obtain

$$\nabla D_n(a_1, \cdots, a_{n-1}) = 0$$

such that $a_1, \cdots, a_{n-1}$ solve the equation

$$x^2 - (A_n + A_n^{\frac{1-q}{q}})x + G_n^{\frac{1}{q}} = 0. \tag{3.6}$$

The above equation has at most two roots(regarding A_n, G_n as constants), so we are reduced to the case $n = 3$. But if $a_1 < a_2 < 1$ both satisfy (3.6), we will have

$$a_1 a_2 = a_1^{\omega_1/q} a_2^{\omega_2/q},$$

which is impossible since $\omega_1 \geq q, \omega_2 \geq q$ and the two equalities can's hold at the same time. Thus if $a_1 > 0$, we only need to prove $D_2 \geq 0$. In this case if $x = a_1 > 0$ and $\omega_1 = 1-q, \omega_2 = q$ then

$$g(x) := x + G_2^{\frac{1}{q}}/x = A_2^{\frac{1-q}{q}} + A_2.$$

Note for $x \leq u, q \leq 1/3$,

$$g'(u) = 1 - G_2^{\frac{1}{q}}/u^2 \geq g'(x) \geq 0,$$

since $0 < x < 1$ and $G_2 = x^{1-q}$. Since $x \leq A_2$ in our case, we then have $g(x) \leq g(A_2) = A_2 + G_2^{\frac{1}{q}}/A_2$, a contradiction.

Now suppose $q > 1/3$, then

$$D_2''(x) = \frac{1-q}{q^2}(q^2 - (1-q)^2 A_2^{\frac{1-2q}{q}} + (1-2q)x^{\frac{1-3q}{q}}) \geq \frac{1-q}{q^2}(q^2 - (1-q)^2 + (1-2q)) = 0,$$

with equality holding if and only if $q = 1/2$. As $D_2(1) = D_2'(1) = 0$, this shows $D_2(x) \geq 0$ by considering the Taylor expansion of D_2 at 1.

Now suppose $\omega_1 = q, \omega_2 = 1-q$, then $D_2''(x) = (1-q)(1 - A_2^{\frac{1-2q}{q}}) \geq 0$ with equality holding if and only if $q = 1/2$. As we also have $D_2(1) = D_2'(1) = 0$, this shows $D_2(x) \geq 0$.

Finally, we consider the case when D_n reaches its absolute minimum at $\mathbf{a}$ with $a_1 = 0$. Define

$$E_n(x_1 = 0, \cdots, x_{n-1}) = \frac{1}{2q}\sigma_n - A_n^{\frac{1}{q}}.$$

We show now $E_n \geq 0$. $E_2 \geq 0$ is equivalent to $g(q) = (1-q)/2 - q^{1/q} \geq 0$ and $(1-q)/2 - (1-q)^{1/q} \geq 0$, the second inequality follows from Lemma 2.2 and one checks $g(q)$ is a decreasing function of q so that $g(q) \geq g(1/2) = 0$ with equality holding if and only if $q = 1/2$.

Suppose now $n \geq 3$ and let $\mathbf{a} = (a_2, \cdots, a_{n-1}) \in [0,1]^{n-3}, 0 < a_2 < \cdots < a_{n-1} < 1$ be the point in which the absolute minimum of E_n is reached. Then

$$\nabla E_n(a_2, \cdots, a_{n-1}) = 0$$

such that $a_2, \cdots, a_{n-1}$ solve the equation

$$x - A_n - A_n^{\frac{1-q}{q}} = 0.$$

The above equation has at most one root(regarding A_n, G_n as constants). Thus it suffices to show $E_3 \geq 0$ under the condition $\omega_i \geq q$. Now $a_2 - A_3 = A_3^{\frac{1-q}{q}}$ and

$$\begin{aligned} E_3 &= \sum_{i=1}^{3} \omega_i (a_i - A_3)^2/2q - A_3^{1/q} \geq A_3^{\frac{2-2q}{q}} + A_3^2/2 - A_3^{1/q} \\ &\geq 2\sqrt{A_3^{\frac{2-2q}{q}} \cdot A_3^2/2} - A_3^{1/q} = (\sqrt{2}-1)A_3^{1/q} \geq 0. \end{aligned}$$

This completes the proof for the left-hand side inequality of (3.5) and for the right-hand side inequality of (3.5), we may again assume $0 \leq x_1 < x_2 < \cdots < x_n = 1$ and define

$$F_n(x_1, \cdots, x_n) = (A_n^{\frac{1}{q}} - G_n^{\frac{1}{q}}) - x_1^{\frac{1}{q}-2}\sigma_n/2q. \tag{3.7}$$

We want to show $F_n \geq 0$. Let $\mathbf{a} = (a_1, \cdots, a_{n-1}) \in [0,1]^{n-1}$ be the point in which the absolute minimum of F_n is reached.

Again we may assume $a_1 < a_2 < \cdots < a_{n-1} < 1$. If $a_1 > 0$ then $\mathbf{a}$ is an interior point of $[0,1]^{n-1}$, and we obtain

$$\nabla F_n(a_1, \cdots, a_{n-1}) = 0$$

such that $a_2, \cdots, a_{n-1}$ solve the equation $f(x) = 0$ where

$$f(x) = a_1^{\frac{1}{q}-2}x^2 - (A_n^{\frac{1}{q}-1} + a_1^{\frac{1}{q}-2}A_n)x + G_n^{\frac{1}{q}}.$$

The above equation has at most two roots(regarding a_1, A_n, G_n as constants), so we are reduced to the case $n = 4$. But note we also have $f(a_1) = -\omega_1^{-1}(\frac{1}{q} - 2)a_1^{\frac{1}{q}-2}\sigma_n \leq 0$ and $f(0) \geq 0$. Thus we only need to consider the case $n = 3$. In this case a_2 is a root of $f(x) = 0$ and the other root c satisfies $0 < c \leq a_1$. But then we will have

$$a_1 a_2 \geq c a_2 = a_1^{\frac{\omega_1}{q}} a_2^{\frac{\omega_2}{q}} a_1^{2-\frac{1}{q}},$$

which implies

$$a_2^{1-\omega_2/q} \geq a_1^{1+(\omega_1-1)/q},$$

which is impossible. Thus if $a_1 > 0$, we only need to prove $F_2 \geq 0$. By renormalizing $a_1 = 1, a_2 > 1$, this case follows similarly to our treatment of $D_2 \geq 0$.

If $\mathbf{a}$ is a boundary point of $[0,1]^{n-1}$, then $a_1 = 0$, (3.7) follows trivially and this completes the proof for the right-hand side inequality of (3.5). □

The following corollary generalizes Theorem 1.2, the proof is similar to that of Corollary 3.1.

Corollary 3.2. *For* $0 < q \leq \min\{\omega_i\}, 0 < x_1 \leq x_2 \leq \cdots \leq x_n < 1, x_1 \neq x_n$,

$$(\frac{x_n}{1-x_n})^{\frac{1}{q}-2} \geq \frac{A_n^{\frac{1}{q}} - G_n^{\frac{1}{q}}}{A_n'^{\frac{1}{q}} - G_n'^{\frac{1}{q}}} \geq (\frac{x_1}{1-x_1})^{\frac{1}{q}-2}.$$

4. Some Inequalities among Symmetric Means

Let $s \in \{0, 1, \cdots, n\}$, the s-th symmetric function E_s of $\mathbf{x}$ and its mean P_s are defined by

$$E_s(\mathbf{x}) = \sum_{1 \leq i_1 < \cdots < i_s \leq n} \prod_{j=1}^{s} x_{i_j}, E_0 = 1; P_s(\mathbf{x}) = \frac{E_r(\mathbf{x})}{\binom{n}{2}}.$$

As mentioned in section 1, we shall write P_s for $P_s(\mathbf{x})$ and the meaning of $P'_s, P_{s,t}$ are similar. Theorem 1.2 can be generalized to inequalities involving the symmetric means.

Theorem 4.1. *For* $n > 1, \omega_i = 1/n, 0 < x_1 \leq x_2 \leq \cdots \leq x_n, t \geq 0,\ 2 \leq r \leq n$.

$$(\frac{x_1}{1-x_1})^{r-2}(A_n'^r - P'_r) \leq \quad A_n^r - P_r \quad \leq (\frac{x_n}{1-x_n})^{r-2}(A_n'^r - P'_r), \tag{4.1}$$

$$(\frac{x_1}{t+x_1})^{r-2}(A_{n,t}^r - P_{r,t}) \leq \quad A_n^r - P_r \quad \leq (\frac{x_n}{t+x_n})^{r-2}(A_{n,t}^r - P_{r,t}), \tag{4.2}$$

$$\frac{r(r-1)x_1^{r-2}}{2(n-1)}\sigma_n \leq \quad A_n^r - P_r \quad \leq \frac{r(r-1)x_n^{r-2}}{2(n-1)}\sigma_n, \tag{4.3}$$

where we need $x_n < 1$ *in* (4.1).

Proof. We note (4.3) is a result of Dinghas[5], originally written as

$$\frac{r(r-1)x_1^{r-2}}{2n(n-1)} \sum_{k=1}^{n} (1-\frac{1}{k})(x_k - A_{k-1})^2 \leq A_n^r - P_r \leq \frac{r(r-1)x_n^{r-2}}{2n(n-1)} \sum_{k=1}^{n} (1-\frac{1}{k})(x_k - A_{k-1})^2.$$

By using the relation $(k-1)A_{k-1} + a_k = A_k$, one shows easily by induction that $\sum_{k=1}^{n}(1 - \frac{1}{k})(x_k - A_{k-1})^2 = n\sigma_n$ and (4.3) then follows. Applying (4.3) to both $A_n^r - P_r$ and $A_n'^r - P'_r$ and take their quotients, we obtain (4.1). To show (4.2), we use another identity of Dinghas[5]:

$$A_n^r - P_r = \frac{\binom{n-2}{r-s}}{\binom{n}{r}} \sum_{k=2}^{n} \sum_{i=2}^{k} (i-1)\frac{(x_k - A_{k-1})^2}{k^2} P_{r-2,n-2}^{i-2,k-i}(A_{k-1}; A_k; x_{k+1}, \cdots, x_n) \tag{4.4}$$

where $P_{r-2,n-2}^{i-2,k-i}(A_{k-1}; A_k; x_{k+1}, \cdots, x_n)$ denotes the $(r-2)$-th symmetric mean of the $n-2$ numbers $A_{k-1}(i-2$ times$)$, $A_k(k-i$ times$)$ and $x_{k+1}, \cdots, x_n$.

Now use (4.4) for $(A_n^r - P_r)/x_n^{r-2}$ and $(A_{n,t}^r - P_{r,t})/(x_n+t)^{r-2}$ and consider their differences, the right-hand side inequality of (4.2) follows from this and the observation

$$\frac{x_i}{x_n} \leq \frac{x_i + t}{x_n + t}, 1 \leq i \leq n; \frac{A_i}{x_n} \leq \frac{A_{i,t}}{x_n + t}, i = k-1, k.$$

The left-hand side inequality of (4.2) can be shown similarly and this completes the proof. □

We note here (4.2) also implies (4.3). This can be seen by noticing $\lim_{t\to\infty}((x_n+t)^{2-r}(A^r_{n,t}-P_{r,t})=r(r-1)\sigma_n/2(n-1)$.

Corollary 4.1. *For $r\geq 2$,*

$$rx_1(A^{r-1}_n-P_{r-1})\leq (r-2)(A^r_n-P_r)\leq rx_n(A^{r-1}_n-P_{r-1}). \tag{4.5}$$

Proof. Let $f(t)=x^{2-r}_{n,t}(A^r_{n,t}-P_{r,t})$. By (4.2), f is an increasing function of t and $f'(0)\geq 0$ gives the right-hand inequality of (4.5) and the left-hand inequality of (4.5) follows similarly. □

Theorem 4.2. *For $n>1, \omega_i=1/n, 0<x_1\leq x_2\leq\cdots\leq x_n, t\geq 0$, $1\leq r\leq n-1$.*

$$(\frac{x_1}{1-x_1})^{2r-2}(P'^2_r-P'_{r-1}P'_{r+1})\leq P^2_r-P_{r-1}P_{r+1}\leq(\frac{x_n}{1-x_n})^{2r-2}(P'^2_r-P'_{r-1}P'_{r+1}), \tag{4.6}$$
$$(\frac{x_1}{t+x_1})^{2r-2}(P^2_{r,t}-P_{r-1,t}P_{r+1,t})\leq P^2_r-P_{r-1}P_{r+1}\leq(\frac{x_n}{t+x_n})^{2r-2}(P^2_{r,t}-P_{r-1,t}P_{r+1,t}),$$
$$\frac{x_1^{2r-2}}{(n-1)}\sigma_n\leq P^2_r-P_{r-1}P_{r+1}\leq\frac{x_n^{2r-2}}{(n-1)}\sigma_n,$$

where we need $x_n<1$ in (4.6).

Proof. The proof is similar to the proof of Theorem 4.1, once we note the following identity of Muirhead[14](see also [11], Theorem 54).

$$P^2_r-P_{r-1}P_{r+1}=(r(r+1)\binom{n}{r}\binom{n}{r+1})^{-1}\sum_{i=0}^{r-1}\binom{2i}{i}\frac{(r,i)}{i+1},$$

where $(r,i)=\sum x_1^2\cdots x^2_{r-i-1}x_{r-i}\cdots x_{r+i-1}(x_{r+i}-x_{r+i+1})^2$, the summation extending over all products formed from the $\mathbf{x}$ and of the type shown. □

We leave the proof of the following corollary to the reader since it is similar to the one of Corollary 4.1.

Corollary 4.2. *For $2\leq r\leq n-1$,*

$$x_1(P_rP_{r-1}-P_{r-2}P_{r+1})\leq 2(P^2_r-P_{r-1}P_{r+1})\leq x_n(P_rP_{r-1}-P_{r-2}P_{r+1}).$$

5. Further Discussions

Theorem 5.1. *For $-1\leq r\neq 1\leq 2$,*

$$|A_n-M_{n,r}|\geq\frac{|1-r|\sigma_n}{2(dx_n+(1-d)x_1)}, \tag{5.1}$$

For $-1/2\leq r<1$,

$$A_n-M_{n,r}\leq(\frac{d}{x_1}+\frac{1-d}{x_n})\frac{(1-r)\sigma_n}{2}, \tag{5.2}$$

where $d=\max\{(2-r)/3,(1+r)/3\}$ and equality hold in both cases if and only if $x_1=\cdots=x_n$.

Proof. A close look at the proof of Theorem 3.1 in [8] shows that the first inequality holds. Similarly to the argument in the proof of Theorem 3.1 in [8], the proof of (5.2) can be reduced to the case $n=2$. By setting $0<x_1=x\leq x_2=1, \omega_1=q, \omega_2=1-q$, $f(x)=x(qx+1-q-(qx^r+1-q)^{1/r})-(1-r)q(1-q)(d+(1-d)x)(x-1)^2/2$. We need to show $f(x)\leq 0$ for $-1/2\leq r<1$. It's easy to check that $f(1)=f'(1)=f''(1)=0$ and

$$f'''(x)=q(1-q)(1-r)[(q+(1-q)x^{-r})^{\frac{1-3r}{r}}x^{-r-1}((1-q)(1+r)x^{-r}+q(2-r))-3(1-d)].$$

Note $(q+(1-q)x^{-r})^{\frac{1-3r}{r}}x^{-r-1}=(qx^r+(1-q))^{\frac{1-3r}{r}}x^{2r-2}\geq 1$ for $-1\leq r<1$. For $0\leq r\leq 1/2$, $(1-q)(1+r)x^{-r}+q(2-r)\geq 1+r+(1-2r)q\geq r+1$ and for $1/2<r<1$, $(1-q)(1+r)x^{-r}+q(2-r)\geq 1+r+(1-2r)q\geq 2-r$, (5.2) holds for our choice of d. When $-1/2\leq r<0$, we write $f'''(x)$ as

$$f'''(x)=q(1-q)(1-r)[(q+(1-q)x^{-r})^{\frac{1-3r}{r}}x^{-2r-1}((1-q)(1+r)+q(2-r)x^r)-3(1-d)],$$

and the conclusion follows similarly. □

We note here when $r=0$, (5.2) implies (5.1). By writing $f(t)=(d(x_n+t)+(1-d)(x_1+t))(A_{n,t}-G_{n,t})$ and noticing $\lim_{t\to\infty}f(t)=\sigma_n/2$, it suffices to show $f'(t)\leq 0$ or equivalently $A_n-G_n+(dx_n+(1-d)x_1)(1-G_n/H_n)\leq 0$ since $\mathbf{x}$ is arbitrary. Now by repeating the same method we see that (5.2) implies (5.1).

We end this paper by proving the following theorem, part of which was a conjecture of the author in [8].

Theorem 5.2. *For $0<x_1\leq\cdots\leq x_n$, $q=\min\{\omega_i\}$*

$$((1-q)/2x_1+q/2x_n)\sigma_n\geq(A_n-G_n)\geq\sigma_n/2((1-q)x_n+qx_1)$$

Proof. For the right-hand side inequality, (5.1) shows

$$2(2x_n+x_1)(A_n-G_n)\geq 3\sigma_n.$$

Thus when $q\leq 1/3$ we are done. But if $q>1/3$, one must have $n=2$ and one checks by direct calculation(see the proof of Theorem 3.1 in [8], replacing c by $2q$ there) that the above conjecture holds for $n=2$. The proof for the left-hand side inequality is similar. □
