Running head: SET-SHOT GOAL-KICKING

A Notational Analysis of Set-Shot Goal-kicking in the Australian Football League

A Notational Analysis of Set-Shot Goal-kicking in the Australian Football League

Abstract

Set-shot goal-kicking is recognized as an important skill in Australian football, accounting for over half of all goals kicked in the Australian Football League (AFL). However, as knowledge surrounding its performance is limited, this study described the frequency, types and outcomes of set-shots in the AFL, and investigated the impact of task, personal, and environmental constraints on goal-kicking performance. We analyzed video footage of set-shots from all 198 AFL 2012 matches, collecting data for kick distance, kick angle, player position, player experience (i.e., general and specific), kick outcome, and weather status. We found an average of 23.0 (SD = 4.5) set-shots/match, with a mean accuracy of 55.0% (SD = 0.7%). Kicking accuracy decreased with incremental increases in kick distance, with accuracy ranging from 97% (0-15m) to 36% (≥ 50 m). Key forwards were more accurate kickers than other players. There was no significant effect of player experience. The number of set-shots taken decreased by 13% in wet weather conditions. The primary determinant of elite set-shot goal-kicking performance was the interaction of kick distance and angle (task difficulty). This research adds to an understanding of how personal, environmental and match constraints influence this closed skill performance in Australian Football match-play.

Keywords: Constraints; Goal-kicking; Performance Analysis; Coaching; Tactical

Introduction

Success within an Australian Football (AF) game is achieved in part by kicking more goals. Although many kicks at actively defended goals are performed during free-play, *set-shots* refer to free goal kicks after markings, in which the player is given up to thirty seconds to perform the kick without threat of being actively defended (Robertson, Back & Bartlett, 2016). Set-shot goal-kicking forms a vital part of Australian Football (AF) match play, accounting for 54% of all goals scored since 2007, with a reported accuracy rate of 61% (Champion Data, 2012). A limitation of this statistic is that it consistently fails to incorporate those most inaccurate shots that are kicked out-of-bounds or fail to make the distance, leading to an overstated accuracy estimate. Despite the match outcome significance of set-shot goal-kicking, no studies have reported detailed data regarding set-shot goal-kicking nor thoroughly considered various environmental performance influences.

AF set-shot performance can be viewed from a dynamic systems approach, specifically the constraints-led approach, to skill performance (Travassos, Duarte, Vilar, Davids, & Araújo, 2012). This approach describes how task, personal and environmental constraints dynamically interact to organize movement (Davids, Button & Bennett, 2008). Task constraints include match-specific aims, rules, and equipment, such as trying to maximise the number of points scored, the fixed location of the set-shot, and the set-shot time limit (Breed & Spittle, 2011; Travassos et al., 2012). Personal constraints include traits such as experience, anthropometry, anxiety, and decision-making skills (Breed & Spittle, 2011). Environmental constraints can include wind, rain, crowd noise, and the stadium where the match is contested (Breed & Spittle, 2011). Constraints may benefit or hinder movement, depending on the situation; and they are rarely independent (Breed & Spittle, 2011). For example, a player may balance perceived kicking ability with location and wind direction to assess if a set-shot forms an optimal scoring opportunity at that point in the match. Therefore, research exploring set-shot motor skill execution should consider the relevant constraints, some of which may be manipulated in practice, to help develop better game play (Breed & Spittle, 2011; Travassos, et al., 2012).

Match-based (task) constraints are specific to the match-play of each sport. Aside from the rules surrounding set-shot performance, such as the time limit for performance, a player is generally limited by the location where they can perform the set-shot. This location can influence the perceived task difficulty, which is regarded to be an interaction between the angle and distance from goal at the point where the kick is taken (Galbraith & Lockwood, 2010; Jackson, 2003). Galbraith and Lockwood attempted to describe this interaction by exploring the angle of opportunity of a given kick, the angle subtended by the goal-line, and the player's point of contact

1 with the ball (see Figure 1; Galbraith & Lockwood, 2010). The angle of opportunity decreases as
2 either kick distance or angle increase, and it can therefore be thought of as the margin for error in
3 the longitudinal (z) axis. This concept was shown to be a valid indicator of kick difficulty in rugby
4 union (Jackson, 2003).

5 <<<INSERT FIGURE 1 HERE>>>

6 Variations in elite AF set-shot goal-kicking accuracy across distance and angle have been
7 reported previously (Bedford & Schembri, 2006), although only scoring shots have been analysed.
8 As noted, earlier this data has neglected the most inaccurate kicks that land out-of-bounds or short
9 and in the field-of-play. Bedford and Schembri (2006) observed that set-shot goal-kicking accuracy
10 decreased progressively as distance from the goal increased for set-shots up to 45° in angle. There
11 were non-significant differences in accuracy for set-shots taken from the boundary line as kick
12 distance increased (Bedford & Schembri, 2006), likely due to the small sample of kicks in these
13 regions and the curved nature of the boundary line that results in angle decreases with increasing
14 distance.

15 Important personal constraints to an ideal performance (Davids, et al., 2008) can be role-
16 oriented (e.g., player position) or psychosocial (e.g., experience). Players in team sports adopt
17 positional roles based on certain anthropometric, physical and tactical requirements of the role
18 (Gabbett, King, & Jenkins, 2008; Gray & Jenkins, 2010) and any distinctive technical skill elements
19 that may help explain why players are selected for particular positions (Jordet, Hartman, Visscher,
20 & Lemmink, 2007). While various physiological demands of different AF playing positions have
21 been reported previously (Dawson, Hopkinson, Appleby, Stewart, & Roberts, 2004; Wisbey, Pyne,
22 & Rattray, 2011), research regarding technical performance in AF matches is far less extensive.
23 However, findings from elite AF matches have demonstrated that players in key forward and
24 ruckman roles were involved in approximately 15 marking opportunities per match, compared to
25 only six per match for smaller midfielders (Appleby & Dawson, 2002). Since set-shots only arise
26 from a successful mark or free kick, it is likely that key forward and ruck players perform
27 proportionately more set-shots than players in midfield and other roles. Greater experience
28 performing match-related set-shots for—key forward and ruck players suggests that they may be
29 more accurate with set-shots than players in other positional roles. Bedford and Schembri (2006)
30 found that ‘specialist’ AFL goal-kickers were more accurate goal-kickers than players in other
31 positions, although these statistics did not isolate set-shot goal-kicking performance. Clearly, more
32 research is required to describe the influence of player position on the frequency and accuracy of
33 set-shot goal-kicking performance in AF.

1 In addition to the foregoing constraints, a greater amount of experience at the elite level of
2 play also provides an athlete with greater exposure to performing under the environmental
3 constraints and pressures associated with elite competition. Gabbett and Ryan (2009) observed that
4 experienced professional rugby league players exhibited superior tackling technique and missed
5 fewer tackles in matches than less experienced players. Despite a logical expectation that greater
6 experience should be associated with improved set-shot goal-kicking, the relationship between
7 performance and elite level AF experience has yet to be investigated.

8 One enduring attribute of skilled athletes is their capacity to adapt to the varying elements in
9 the performance environment (Davids, et al., 2008). Rainfall is one typically encountered
10 environmental condition for AF players that may affect match-play and skill performance. Appleby
11 and Dawson (2002) observed a nine percent drop in contested marking efficiency in wet conditions
12 compared to dry conditions. A reduction in the number of marks taken during a match is likely to
13 reduce the number of set-shots performed. For the set-shots that are taken in wet conditions, it is
14 probable that a wet and heavier ball will be more difficult to grip and require more force for a
15 required distance than a ball in dry conditions (Orchard, 2001).

16 Despite the importance of set-shot goal-kicking in winning Australian Football matches, to
17 date, no studies have observed and reported on set-shot goal-kicking in sufficient detail nor
18 thoroughly considered various performance constraints that can influence skill execution. Further,
19 no investigations have provided a full report of set-shot goal-kicking performance that includes
20 non-scoring set-shots. Therefore, this study aimed to describe the frequency, types and outcomes
21 of set-shots in the Australian Football League, and to investigate the impact of task, personal and
22 environmental constraints on elite set-shot goal-kicking performance.

23 **Method**

24 **Instruments**

25 We used a between-group observational design to quantitatively examine the population
26 of all set-shots taken during all 198 matches of the 2012 AFL season, using a single observer's
27 ratings of a combination of television broadcast and behind-the-goals video footage (i.e.,
28 footage from an elevated, fixed camera available to all AFL clubs). Video footage was viewed
29 within SportsCode v.8 software (Sportstec, Sydney, Australia), with the footage paused,
30 slowed or replayed to maximize the integrity of data collection.

31 **Sample selection**

32 As noted above, a set-shot is a kick for goal which follows a mark or free kick; the player is
33 given up to 30 seconds to perform the kick without threat of being actively defended. We applied

1 strict inclusion criteria to ensure all kicks were set-shots at goal. This included consideration of
2 several temporal and behavioral cues to determine whether the player intended to kick a goal, pass
3 or gain territory. Cues indicative of the intent to kick a goal and leading to data inclusion were:
4 absence of urgency in kick preparation (e.g., a routine time longer than 15 seconds), presence
5 of ritualistic behavioral idiosyncrasies (e.g., set-shot routine, placing the ball on the ground,
6 refitting socks and throwing blades of glass), and eyes focused on the goal. Kicks were
7 excluded from data analysis if the player attempted to pass the ball, the kicker was deemed to
8 have moved off his direct line toward the goal and/or the umpire called ‘play on’ (as this call
9 allowed the opposition to tackle the kicker and removed the stability of the free kick environment
10 so that the set-shot was no longer a predominantly closed skill). In addition, data were excluded
11 from analysis if there were any of several cues generally indicative of the player’s intent to pass
12 the ball or gain territory, including: a hurried kick preparation, a lack of any ritualistic
13 behavioral idiosyncrasies, and eyes scanning the field-of-play for passing options. Finally, we
14 excluded kicks taken after the siren (i.e., signalling the end of a quarter) unless the observer
15 believed the player would have performed a set-shot if all other options (i.e., pass or play on)
16 had still been available.

17 **Data collection**

18 Each time a set-shot was performed, kick outcome and details regarding task, personal
19 and environmental constraints were recorded. To establish if there were differences in set-shot
20 frequency and accuracy between winning and losing teams, we divided set-shots from each
21 match into those taken by winning and losing teams. One drawn match was excluded from this
22 analysis.

23 We scored kick outcome, based on the AFL scoring system whereby a goal (i.e., a kick
24 by a player which passes unimpeded between the two large goalposts) was scored as six points;
25 a “behind” (i.e., a kick that either struck a large goalpost, or passed unimpeded within the
26 bounds of a smaller ‘behind post’ on either side of the large goalposts) was scored as one point;
27 and both a kick that fell short (i.e., a kick that was touched inside the field-of-play by any
28 player) or went out-of-bounds (i.e., a kick which either struck a behind post or landed outside
29 of the field-of-play without registering a score) was scored as zero points (Figure 2). The only
30 accuracy measurement was a kick that achieved a goal.

31 <<<INSERT FIGURE 2 HERE>>>

1 To determine the task constraints of each kick, we classified the kicking location into 15
2 zones, based on distance and angle. Kick distance categories were 0-15 meters (m), 15-30 m,
3 30-40 m, 40-50 m and 50+ m, based on the distance from the goal-line at the time of
4 performance. The acuity of the kicking angle was judged relative to the nearest goalpost into
5 angles less than 30° ('in front of goal'), and 30° or more ('acute angle') with either a left or
6 right vector (see Figure 3) (Nicholls, Loetscher, & Rademacher, 2010). We assessed inter-
7 observer reliability by cross-checking the locations of scoring shots (n = 4094) with those
8 logged by official AFL statisticians Champion Data. Inter-observer agreement (with Cohen's
9 kappa) for kick distance and angle categories were 96.6% ($\kappa = 0.93$) and 98.3% ($\kappa = 0.97$),
10 respectively. We assessed intra-observer reliability by having the observer re-analyze set-shots
11 from four randomly selected matches (n = 98) six months after the initial observations. Intra-
12 observer agreement (with Cohen's kappa) for kick distance and angle categories were 87.8%
13 ($\kappa = 0.75$) and 88.8% ($\kappa = 0.77$), respectively. Thus, inter- and intra-observer reliability was
14 excellent for this notational analysis (Fleiss, 1981).

15 To assess personal constraints, in conjunction with an AFL high performance coach, we
16 categorized players according to their playing positions into 'key forwards' and 'other players.'
17 To assist with assigning players to a category, we adopted the same line of questioning as
18 Jordet et al. (2007): "Is the player's primary task to score goals (key forwards) or to set up
19 others (other players)?" The number of AFL games played and goals kicked by the player
20 performing the set-shot as of January 1, 2012 (just prior to the analysis period) were recorded as
21 measures of general (i.e., games) and specific (i.e., goals kicked) experience. Both datasets were
22 derived from the official AFL Record and were divided into the following frequency categories: 0,
23 1-49, 50-99, 100-149 and 150+.

24 Weather related (i.e., rainfall) environmental constraint measures were based on rainfall
25 data from the Bureau of Meteorology, with data from the nearest weather station (mean distance
26 from stadium = 7.5 kilometers (km), $SD = 5.9$) used for analysis (Orchard, 2001; Orchard & Powell,
27 2003). We applied conservative arbitrary threshold values following preliminary examination of
28 rainfall observations, with match conditions classified as wet if rainfall exceeded 1.5 millimetres
29 (mm) during the match, or if rainfall exceeded 2.0 mm in the four hours prior to the match
30 commencing. All classifications of weather conditions were verified by visual inspection of the
31 match footage.

1 Statistical analyses

2 All statistical analyses were performed using SPSS[®] v.20 (IBM Corporation, Armonk
3 NY, USA) for Windows[®]/Apple Mac[®]. For some analyses, kick locations were grouped
4 according to difficulty into low probability shot locations (i.e., lowest tercile for mean
5 accuracy) and moderate-to-high probability set-shot locations (i.e., middle and upper tercile)
6 (Figure 3). Significance levels for all variables were set at $p < 0.05$.

7 Set-shot accuracy was defined as the percent (%) of goals scored from all set-shots
8 (presented as means and standard errors). Due to the dichotomous nature of the dataset, we
9 used non-parametric Pearson's chi-squared independence tests (χ^2) to determine which (if any)
10 personal, environmental or task constraints affected set-shot goal-kicking accuracy. We used
11 Bonferroni-adjusted chi-square tests for post-hoc comparisons, if required. We calculated odds
12 ratios (*OR*) as a measure of effect size for all accuracy comparisons between groups. The same
13 statistical measures were used to report data on set-shot selection, stated as the proportion of
14 low probability set-shots (LPS) taken under a particular condition.

15 For selected variables, we also analyzed the frequency of set-shots (shots per
16 quarter/match). Since Shapiro-Wilk tests revealed normality of the data distribution for the
17 frequency of shots when grouped by weather status, we compared the frequency of set-shots
18 under various weather conditions using means and standard deviations in parametric one-way
19 analyses of variance (ANOVA) with post-hoc Bonferroni-adjusted independent *t*-tests. We
20 confirmed equality of variance for these variables through Levene's test ($p > .05$). Effect sizes
21 for parametric and non-parametric tests were given as Cohen's *d* and eta-squared (η^2),
22 respectively.

23 Results

24 A total of 4,599 set-shots were taken during the 2012 AFL home-and-away season, with
25 an average of 23.2 (SD = 4.6) occurring per match; set shots had a mean accuracy rate of 55.0%
26 (SD = 0.7%). Inaccurate kicks were comprised of behinds (Mean = 33.7%, SD = 0.7%),
27 kicks that fell short (Mean = 8.2%, SD = 0.4%) or kicks that were out-of-bounds (Mean =
28 3.1%, SD = 0.3%).

29 Winning teams kicked more accurately (Mean = 57.5%, SD = 0.9%) from set-shots
30 than did losing teams (Mean = 51.0%, SD = 1.2%), $\chi^2(1, N = 4570) = 18.40, p < 0.001, OR =$
31 1.30, and performed more set-shots per match (Mean = 14.0, SD = 3.8; Range = 6.0-26.0) than

1 losing teams (Mean = 9.0, SD = 3.4; Range = 2.0-20.0), $H(1, 394) = 128.67, p < .001, \eta^2 =$
 2 .327. Yet, there was no notable difference between winning and losing teams for shot selection.
 3 Losing teams performed an average of 32.3% of their set-shots from low probability locations,
 4 compared with 31.5% by winning teams, $\chi^2(1, N = 4570) = 0.353, p = 0.55, OR = 1.04$. Nearly
 5 one third of winning teams (33%) were able to win their match despite being less accurate from
 6 set-shots than their opponents, although teams that performed a lower number of set-shots won,
 7 on average, only 13% of the time.

8 <<<INSERT FIGURE 3 HERE>>>

9 **Task constraints**

10 Set-shot accuracy decreased consistently as kick distance increased, $\chi^2(4, N = 4599) =$
 11 440.20, $p < 0.001$ (Figure 3). Set-shots were most frequently taken between 40-49 meters (n =
 12 1876), accounting for 41% of all set-shots (Figure 3). Set-shots were taken least frequently
 13 between 0-15 meters (n = 186), making up just 4% of the sample. Set-shots taken on acute
 14 angles were, on average, 24% (n = 634; $M_{\text{per match}} = 3.2$; $SD_{\text{per match}} = 1.9$) less accurate than
 15 those taken in front of goal (n = 1893; $M_{\text{per match}} = 9.5$; $SD_{\text{per match}} = 3.1$) $\chi^2(1, N = 4599) =$
 16 232.68, $p < 0.001, OR = 2.61$. On average, this equates to an extra 1.3 points to the offensive
 17 team for every set-shot they produce towards the middle of the field.

18 **Personal constraints**

19 Key forwards performed an average of 56% (SD = 1.0%) of all set-shots, but there was
 20 no overall significant effect of player position on set-shot accuracy, $\chi^2(1, N = 4599) = 3.03, p$
 21 $= .08, OR = 1.11$. Similarly, key forwards were, on average, six percent more accurate than
 22 other players in front of the goal, $\chi^2(1, N = 4599) = 12.82, p < .001, OR = 1.32$, but key
 23 forwards were no more accurate than other players on angles $\geq 30^\circ$, $\chi^2(1, N = 4599) = 0.31, p$
 24 $= .58, OR = 0.99$ (Table 1). Key forwards performed an average of 32% (n = 859; $M_{\text{per match}} =$
 25 4.3; $SD_{\text{per match}} = 2.2$) of set-shots from low probability locations, compared to 31% (n = 603;
 26 $M_{\text{per match}} = 3.1$; $SD_{\text{per match}} = 1.7$) by other players, $\chi^2(1, N = 4599) = 1.22, p = .27, OR = 1.08$.

27 <<<INSERT TABLE 1 HERE>>>

28 The number of AFL games played by the kicker did not influence set-shot goal-kicking
 29 accuracy, $\chi^2(4, N = 4599) = 6.13, p = .19$. Similarly, the number of goals scored at an AFL
 30 level by the kicker did not affect set-shot goal-kicking accuracy, $\chi^2(4, N = 4599) = 5.83, p =$
 31 .25 (Table 2). However, there was a significant effect of general experience, $\chi^2(4, N = 4599) =$

1 14.82, $p = .005$; and specific experience, $\chi^2(4, N = 4599) = 17.78, p = .001$, for set-shot selection
 2 (Table 2). For general experience, post-hoc chi-square tests (Bonferroni-adjusted $p < 0.02$) showed
 3 that players with ≥ 150 AFL games of experience performed a greater proportion of low probability
 4 set-shots than players who had played 1-49 AFL games, $\chi^2(1, N = 2385) = 7.88, p = .005, OR =$
 5 1.28 ; or 50-99 AFL games, $\chi^2(1, N = 2041) = 13.79, p < .001, OR = 1.42$. For specific experience,
 6 players with ≥ 150 AFL goals kicked took a greater proportion of low probability set-shots than
 7 players who had kicked 1-49 AFL goals, $\chi^2(1, N = 2824) = 14.46, p < .001, OR = 1.38$; and 100-
 8 149 AFL goals, $\chi^2(1, N = 1525) = 5.79, p = .02, OR = 1.31$. Players who had kicked 50-99 AFL
 9 goals also had a greater proportion of low probability set-shots than players who had kicked 1-49
 10 AFL goals, $\chi^2(1, N = 2653) = 7.20, p = .007, OR = 1.28$.

11 <<<INSERT TABLE 2 HERE>>>

12 **Environmental Constraints**

13 Fourteen matches were played in wet conditions. Results showed a 13% decrease in the
 14 number of set-shots taken during an AFL match in wet conditions, $F(1, 196) = 6.35, p = .01, d$
 15 $= -0.62$, however, kicking accuracy was not affected by wet conditions, $\chi^2(1, N = 4599) = 0.39,$
 16 $p = .53$ (Table 3). Set-shots were no more likely to be performed from low probability locations
 17 in wet conditions (an average of 30% of set-shots), compared with non-wet conditions (32%),
 18 $\chi^2(1, N = 4599) = 0.68, p = .41, OR = 0.90$.

19 <<<INSERT TABLE 3 HERE>>>

20 **Discussion**

21 The purpose of this study was to describe the frequency, types and outcomes of set-shots
 22 in the AFL, and to investigate the impact of task, personal and environmental constraints on
 23 elite set-shot goal-kicking performance. The overall accuracy rate reported in this study (55%)
 24 is six percent lower than the figure reported in official statistics for the 2012 season. This
 25 difference reflects the fact that data within this study included kicks that either landed out-of-
 26 bounds or failed to make the distance and landed in the field-of-play. Kicks of the latter
 27 category may indirectly lead to scores by advancing the ball towards one's attacking goal, but
 28 it was not within the scope of this study to examine the passages of play immediately following
 29 an inaccurate set-shot. Preparing for a set-shot allows the defensive team to place extra
 30 defenders close to the attacking goal, so a player performing a set-shot consciously decides
 31 whether his set-shot forms the optimal scoring opportunity for his team in that offensive
 32 possession. Kicks that fell short are therefore likely to have been some combination of an error

1 in perceptual decision-making (perception of ability to kick the required distance) and/or error
2 in skill execution. Since just over a quarter of set-shots greater than 50 meters landed in the
3 field-of-play, teams might be better advised to plan offensive and defensive strategies when
4 the ball lands in the field-of-play.

5 These analyses showed set-shot goal-kicking performance to be linked with ultimately
6 winning matches. Winning teams averaged 4.5 more set-shots during matches than losing
7 teams, possibly due to a higher quantity and/or quality of possession in their team's attacking
8 half, combined with superior contested marking ability. Our results also revealed that winning
9 teams were, on average, seven percent more accurate from set-shots than losing teams. Since
10 scoring outcomes contribute directly to match outcomes, this finding may seem overt and self-
11 explanatory. This accuracy difference, however, only equates to approximately 0.4 points per
12 set-shot on average, which suggests other mechanisms such as opposition quality may also
13 influence these results. We conducted an exploratory analysis to control for opposition quality
14 by removing data from the top four and bottom four teams in the competition rankings at the
15 end of the home-and-away season, and the pattern remained.

16 There was an evident inverse relationship between kick distance and kicking accuracy,
17 replicating findings in AF data (Bedford & Schembri, 2006) and rugby union data (Jackson,
18 2003). As kick distance increases, the angle of opportunity (and therefore margin for error)
19 decreases (Galbraith & Lockwood, 2010), and the proportion of kicks that fail to make the
20 distance also increase. Without controlling for these factors, it is difficult to rule out the
21 influence of a speed-accuracy trade-off, although previous studies (García, Sabido, Barbado,
22 & Moreno, 2011; Landlinger, Stöggl, Lindinger, Wagner, & Müller, 2011; Zebas & Nelson,
23 1988) suggest that elite team sport athletes in striking, throwing and kicking tasks can maintain
24 similar accuracy levels whilst aiming for maximal force production.

25 Our results showed set-shots were most frequently taken at distances between 40-49
26 meters from the goal. A likely explanation for this is that set-shots from greater distances (50+
27 meters) are beyond the kicking range of most professional AF players, and marking
28 opportunities which result in set-shots of shorter distances (< 40 meters) are defended more
29 diligently by the opposing team. Examining Figure 3, an argument can be made that, in many
30 cases, teams can enhance their probability of scoring a goal if they can successfully maintain
31 possession and attain a set-shot from a greater distance with a reduced angle. This may seem
32 counterintuitive, given the propensity to gain territory towards one's goal; but since just over
33 30% of set-shots currently performed are from locations with an average success rate of 37%

1 and yield only 2.6 points on average for the offensive team, coaches should consider other
2 strategies to score goals in AF.

3 AF players were, on average, 2.6 times more likely to score a goal from a set-shot when the
4 angle was less than 30°, compared with more acute angles. Comparable to our findings for kick
5 distance, this can be attributed to a reduction in relative width of the goal-line for each increase in
6 angle at a given distance from goal (Galbraith & Lockwood, 2010). Clearly, teams should adopt
7 defensive tactics that minimize marking opportunities in front of the goal. There were a
8 proportionately lower number of set-shots taken on acute angles when the player was less than 30
9 meters from goal, compared with set-shots of greater distances. An observation from the data
10 collection was that the majority of players adopted a different kicking technique to the traditional
11 drop punt kicking style for set-shots closer than 30 meters from the goal. There were various
12 differentiations noticed, but the common feature was that players attempted to improve the angle
13 of the kick by ‘playing on’ and utilizing a five-meter protected area around the kicker.

14 When considering player positions, key forwards performed set-shots more frequently
15 than players in other positional roles. By definition, these players are the target of offensive
16 strategies and as such spend the majority of playing time in their attacking half. This is
17 supported by Appleby and Dawson (2002) who previously found key forwards are involved in
18 more marking opportunities than other players, which would result in more set-shot
19 opportunities. There was selected evidence to support the finding of Bedford and Schembri
20 (2006) that specialist goal-kickers are more accurate when performing set-shots than non-
21 specialists. Key forwards were, on average, six percent more accurate than other players when
22 in front of goal, but they were no more accurate when on acute angles. Previous researchers
23 have attributed trends towards forwards being more accurate goal-kickers to greater task-
24 specific experience (Jordet, et al., 2007). It is reasonable to propose that key forwards would
25 have greater experience in performing set-shots than other players given they perform set-shots
26 more frequently in matches. This experience produced an advantage for lower difficulty set-
27 shots compared to other players, however, this did not translate to an advantage for higher
28 difficulty shots. This suggests that the practice was beneficial for set-shots that were performed
29 from a lower difficulty and key forwards would normally be expected to successfully execute.
30 This benefit was not evident for higher difficulty shots where all players have a similar rate of
31 success. More research is required to assess this relationship and the potential link to practice
32 conditions.

1 Neither the number of AFL games played, nor the number of AFL goals kicked proved
2 advantageous to set-shot goal-kicking performance. Gabbett and Ryan (2009) showed that elite
3 rugby league players with 150 professional games of experience or more were more effective
4 tacklers than players with less than 150 professional games of experience, a finding that was
5 not replicated in the present study. This may be because tackling is a highly open skill requiring
6 a strong perceptual and decision-making component, which may only be refined by extensive
7 exposure to tackling situations at the professional level. The experience of a player was, however,
8 linked to the selection of set-shots. The most experienced players (150+ goals kicked; 150+ games
9 played) were more likely to perform shots from locations with a low probability of success than
10 several of the less experienced groups. This suggests that players in the less experienced groups
11 choose other options (i.e. pass or run with the ball) when set-shot opportunities arise in low
12 probability locations, rather than kick for goal. Due to their experience, it is suggested these players
13 are generally less likely to be the primary offensive target for their team, which would explain the
14 inclination to pass the ball. Alternatively, it is possible that as AFL players gain experience, they
15 become better at discerning which set-shots are within their capabilities. The time course of this
16 study was not sufficient to examine changes in individual set-shot goal-kicking performance
17 as experience develops, however the findings allude to a trend towards AF players not
18 improving their set-shot goal-kicking accuracy once in the AFL system. If such a trend exists,
19 it may be that professional AF teams may not be allocating sufficient practice time to set-shot
20 goal-kicking, or – on the other end of the paradigm – that players enter the AFL system at a
21 relatively high performance level to begin with and experience a diminishing returns effect
22 throughout their career.

23 When considering environmental constraints, results showed the number of set-shots
24 decreased by 13% in wet conditions. Appleby and Dawson (2002) reported the proportion of
25 contested marks dropped increased by nine percent in wet conditions, which would contribute
26 to the decrease in set-shots. There may also be tactical adjustments to the style of AF match-
27 play that occur in wet conditions which affect the number of marking opportunities close to
28 goal resulting in set-shots. Anecdotally, ‘wet-weather football’ in AF consists of more
29 congested match-play, typically resulting in slower ball movement and less effective
30 possession strategies, though this is yet to be described in research literature. Set-shot goal-
31 kicking accuracy was shown to be unaffected by rainy conditions, despite the assumption that
32 a football becomes heavier during rainy matches and more difficult to grasp. This adds
33 evidence to the idea that, similar to throwing (García, et al., 2011) and striking tasks

1 (Landlinger, et al., 2011), elite athletes can maintain kicking accuracy with increasing kicking
2 force.

3 **Strengths and Limitations**

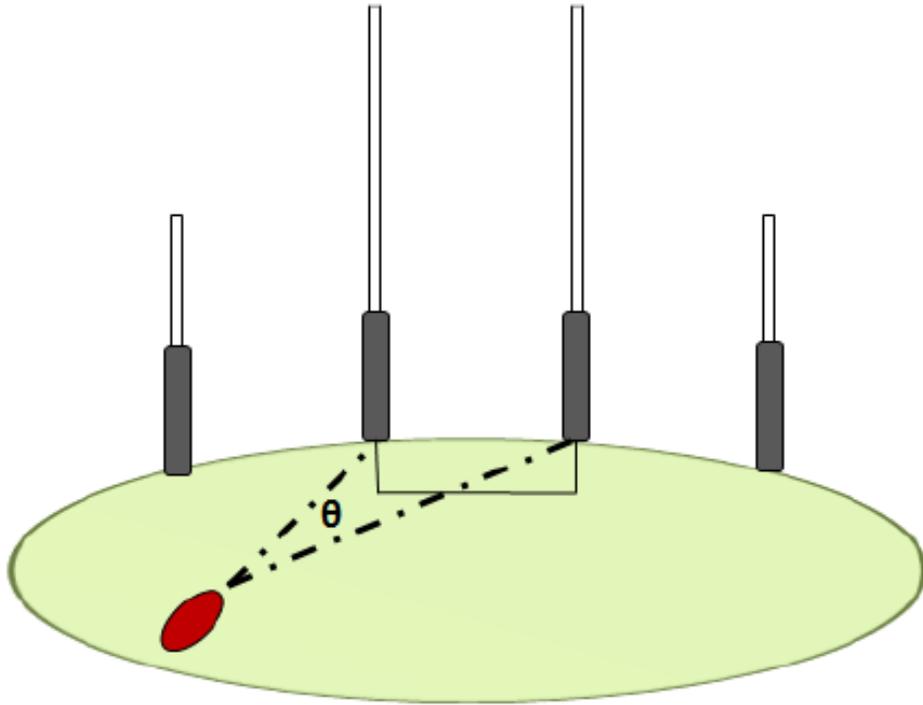

4 This was the first study to show the impact of task, personal and environmental constraints
5 on set-shot goal-kicking performance; this study also provides a more accurate measure of kicking
6 accuracy by including set-shots that are kicked out-of-bounds or fail to make the distance. Set-
7 shot goal-kicking is a predominantly closed skill that must be considered within the context of
8 the performance environment. In contrast to a soccer penalty kick or free throw, set-shot goal-
9 kicking involves a decision-making component in which players must determine if a set-shot
10 maximizes the goal-scoring capabilities of their team for a particular offensive possession.
11 They must balance their own perceived ability with the surrounding offensive and defensive
12 tactics and any constraints that may influence performance. While not an aim of the current
13 study, future research may consider the influence of a player's confidence (or overconfidence)
14 to their set-shot ability when making the decision to attempt a set-shot, and whether this impacts
15 set-shot performance. The primary determinant of elite set-shot goal-kicking performance was
16 shown to be the interaction of kick distance and angle (task difficulty). Skill execution was
17 shown to be relatively stable under various environmental constraints. The frequency of set-
18 shots, however, was shown to be negatively affected by wet playing conditions early in the
19 competitive season and for losing teams. A limitation of this study is that it only sampled set-
20 shots from one AFL season (2012). Additionally, we utilized only one observer for data
21 collection, though inter- and intra-observer reliability data was strongly supportive of such
22 verifiable observations as kicking location judgments. These data are not contemporary, though
23 its findings are still important for athletes and coaches alike, as they involve elite performance
24 in match situations across a national competition. While several potentially relevant variables,
25 including anxiety, perceived momentum and fatigue were not directly assessed, the results of
26 this study may assist with the design of more effective practice environments from a variety of
27 locations and especially from ranges of 40-50 meters. Further, these results may influence
28 technical (i.e., marking ability) and tactical (i.e., offensive structure) strategies employed by
29 coaches to maximize the frequency and accuracy of set-shots.
